6 USE OF SPECIFICATION – TERMS, CONDITIONS & NOTICES

7 The material in this document details an Object Management Group specification in accordance with the terms,  
8 conditions and notices set forth below. This document does not represent a commitment to implement any portion of  
9 this specification in any company's products. The information contained in this document is subject to change  
10 without notice.

11 LICENSES

12 The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-  
13 free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute  
14 copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed  
15 to have infringed the copyright in the included material of any such copyright holder by reason of having used the  
16 specification set forth herein or having conformed any computer software to the specification.

17 Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a  
18 fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use  
19 this specification to create and distribute software and special purpose specifications that are based upon this  
20 specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that:  
21 (1) both the copyright notice identified above and this permission notice appear on any copies of this specification;  
22 (2) the use of the specifications is for informational purposes and will not be copied or posted on any network  
23 computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3)  
24 no modifications are made to this specification. This limited permission automatically terminates without notice if  
25 you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the  
26 specifications in your possession or control.

27 PATENTS

28 The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may  
29 require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which  
30 a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or  
31 scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only.  
32 Prospective users are responsible for protecting themselves against liability for infringement of patents.

33 GENERAL USE RESTRICTIONS

34 Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications  
35 regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved.  
36 No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic,  
37 electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--  
38 without permission of the copyright owner.

1 DISCLAIMER OF WARRANTY

2 WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY  
3 CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES  
4 LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS  
5 PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP,  
6 IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR  
7 PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE  
8 COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT,  
9 INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING  
10 LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN  
11 CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF  
12 ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

13 The entire risk as to the quality and performance of software developed using this specification is borne by you. This  
14 disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

15 RESTRICTED RIGHTS LEGEND

16 Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1)  
17 (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)  
18 (1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified  
19 in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the  
20 Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as  
21 indicated above and may be contacted through the Object Management Group, 140 Kendrick Street, Needham, MA  
22 02494, U.S.A.

23 TRADEMARKS

24 MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are  
25 registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified  
26 Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA  
27 logos™, XMI Logo™, CWM™, CWM Logo™, IIOPTM™, MOFTM™, OMG Interface Definition Language (IDL)™,  
28 and OMG SysML™ are trademarks of the Object Management Group. All other products or company names  
29 mentioned are used for identification purposes only, and may be trademarks of their respective owners.

30 COMPLIANCE

31 The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its  
32 designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer  
33 software to use certification marks, trademarks or other special designations to indicate compliance with these  
34 materials.

35 Software developed under the terms of this license may claim compliance or conformance with this specification if  
36 and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the  
37 specification. Software developed only partially matching the applicable compliance points may claim only that the  
38 software was based on this specification, but may not claim compliance or conformance with this specification. In  
39 the event that testing suites are implemented or approved by Object Management Group, Inc., software developed  
40 using this specification may claim compliance or conformance with the specification only if the software  
41 satisfactorily completes the testing suites.

## OMG's Issue Reporting Procedure

2 All OMG specifications are subject to continuous review and improvement. As part of this process we encourage  
3 readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting  
4 Form listed on the main web page <http://www.omg.org>, under Documents, Report a Bug/Issue ([http://www.omg.org/](http://www.omg.org/technology/agreement)  
5 [technology/agreement](http://www.omg.org/technology/agreement).)

# 1 Preface

## 2 OMG

3 Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer  
4 industry standards consortium that produces and maintains computer industry specifications for interoperable,  
5 portable, and reusable enterprise applications in distributed, heterogeneous environments. Membership includes  
6 Information Technology vendors, end users, government agencies, and academia.

7 OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's  
8 specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle  
9 approach to enterprise integration that covers multiple operating systems, programming languages, middleware and  
10 networking infrastructures, and software development environments. OMG's specifications include: UML®  
11 (Unified Modeling Language™); CORBA® (Common Object Request Broker Architecture); CWM™ (Common  
12 Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

13 More information on the OMG is available at <http://www.omg.org/>.

## 14 OMG Specifications

15 As noted, OMG specifications address middleware, modeling and vertical domain frameworks. A Specifications  
16 Catalog is available from the OMG website at:

17 [http://www.omg.org/technology/documents/spec\\_catalog.htm](http://www.omg.org/technology/documents/spec_catalog.htm)

18 Specifications within the Catalog are organized by the following categories:

### 19 Business Modeling Specifications

- 20 • Business Strategy, Business Rules and Business Process Management Specifications

### 21 Middleware Specifications

- 22 • CORBA/IIOP Specifications
- 23 • Minimum CORBA
- 24 • CORBA Component Model (CCM) Specification
- 25 • Data Distribution Service (DDS) Specifications

### 26 Specialized CORBA Specifications

- 27 • Includes CORBA/e and Realtime and Embedded Systems

### 28 Language Mappings

- 29 • IDL / Language Mapping Specifications
- 30 • Other Language Mapping Specifications

## 1 **Modeling and Metadata Specifications**

- 2 • UML®, MOF, XMI, and CWM Specifications
- 3 • UML Profiles

## 4 **Modernization Specifications**

- 5 • KDM

## 6 **Platform Independent Model (PIM), Platform Specific Model (PSM) and** 7 **Interface Specifications**

- 8 • OMG Domain Specifications
- 9 • CORBA services Specifications
- 10 • CORBA facilities Specifications
- 11 • OMG Embedded Intelligence Specifications
- 12 • OMG Security Specifications

13 All of OMG's formal specifications may be downloaded without charge from our website. (Products implementing  
14 OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and  
15 PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management  
16 Group, Inc. at:

17           OMG Headquarters  
18           140 Kendrick Street  
19           Building A, Suite 300  
20           Needham, MA 02494  
21           USA  
22           Tel: +1-781-444-0404  
23           Fax: +1-781-444-0320  
24           Email: [pubs@omg.org](mailto:pubs@omg.org)

25 Certain OMG specifications are also available as ISO standards. Please consult <http://www.iso.org>

## 26 **Typographical Conventions**

27 The type styles shown below are used in this document to distinguish programming statements from ordinary  
28 English. However, these conventions are not used in tables or section headings where no distinction is necessary.

29 Times/Times New Roman - 10 pt.: Standard body text

30 **Arial - 9 pt. Bold:** OMG Interface Definition Language (OMG IDL) and syntax elements.

31 Arial – 9 pt: Examples

32 NOTE: Terms that appear in *italics* are defined in the glossary. *Italic* text also represents the name of a document,  
33 specification, or other publication.

# 1 Scope

CCM (including lightweight CCM<sup>1</sup>) offers as main features i) to make explicit connections between components and ii) to offer a nice architectural pattern to keep separated the business code from the non-functional properties. This specification deals with the first point, i.e. the supported interactions between components.

In the initial version of CCM the only supported interactions between components were i) synchronous method invocation and ii) events, with no possibility to adjust the behavior of these (e.g., via QoS). A recent extension has added the support for streams. This specification deals with support for DDS interactions. However, rather than specifying an ad-hoc solution for that support, the specification is made of two parts:

- **Firstly, a Generic Interaction Support** allowing to define new interactions in CCM. This support is made of two constructs: i) a new port type (namely *extended port*) to capture as a whole a set of basic interactions that need to be kept consistent (a trivial example is e.g., how to provide message passing with flow control) and ii) abstractions in between components (namely *connectors*) to support new interaction mechanisms. Those extensions are complementary – extended ports being the declarative part (attached to a component definition), while connectors can be seen as their operative part. It should be noted however that both (extended ports and connectors) can be used in isolation, even if maximum benefit results from their combination. Section 7 contains this part of the specification.
- **Secondly, the specialization of those constructs to define DDS support.** This results in the specification of a set of DDS extended ports and connectors. This definition is itself divided in two parts: i) extended ports and connectors for DDS/DCPS and ii) extended ports and connectors for DDS/DLRL. Sections 8 (for DCPS) and 9 (for DLRL) contain this part of the specification.

## 2 Conformance

The conformance criteria of an implementation w.r.t this specification is stated through the support for the following extensions:

1. **A CCM framework claiming conformance with the “Generic Interaction Support”** part of this specification shall support extended ports and connectors:
  - a) Extensions of IDL3 to support **porttype**, **mirrorport** and **port** declarations
  - b) Extension of IDL3 to support parameterized interfaces (template)
  - c) Extension of D&C PSM for CCM to describe extended ports
  - d) Extension of IDL3 to support **connector** declaration
  - e) Extension of D&C PSM for CCM to deploy and configure **connector** fragments
2. **A CCM framework claiming conformance with this “DDS for Lightweight CCM” specification** shall, in addition, support DDS-DCPS normative ports and connectors and their configuration.
3. **An optional compliance point for this “DDS for Lightweight CCM” specification** is the support for DLRL ports and connectors and their configuration.

---

<sup>1</sup> In the remaining document, CCM will implicitly refer also to lightweight CCM .

## 3 Normative References

The following normative documents contain provisions which, through reference in this text, constitute provisions of this specification. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply.

- [CORBA] Common Object Request Broker Architecture: Core Specification, OMG, V3.1, part 1, part 2 and part 3 (formal/08-01-05; formal/08-01-07; formal/08-01-06).
- [UML CCM] UML Profile for CORBA & CORBA Components, v1.0 (formal/08-04-07)
- [CCM] CORBA Component Model Specification, v4.0 (formal/06-04-01); CORBA Component Model, v4.0 XML (formal/07-02-02); CORBA Component Model, v4.0 IDL (formal/07-02-01);
- [IDL] Draft CORBA Core 3.0 consisting of CORBA Core 2.6 + Core and Interop RTF 12/2000 Changes + Components FTF Changes (only the changed chapters are in this document) (ptc/02-01-14)
- [QOS4CCM] Quality of Service for CORBA Components (ptc/07-08-14)
- [D&C] Deployment and Configuration of Component-based Distributed Applications, OMG, V4.0 (formal/06-04-02).
- [DDS] Data Distribution Service for Real-time Systems Specification, OMG, V1.2, (formal/07-07-01).

## 4 Terms and Definitions

In the scope of this specification, the following terms and definitions apply.

- **Connector** – Interaction entity between components. A connector is seen at design level as a connection between components and is composed of several fragments (artifacts) at execution level, to realize the interaction.
- **Extended Port** – Consists of zero or more provided as well as zero or more required interfaces, i.e. closely resembling the UML2 specification of a port.
- **Fragment** – Artifact, part of the connector implementation. A fragment corresponds to one executor that can be deployed onto an execution node, co-localized with one component for which it supports the interaction provided by the connector.

## 5 Symbols (and abbreviated terms)

The followings acronyms are intensely used in the following specification:

- CCM           CORBA Component Model
- CIF           Component Implementation Framework
- CORBA       Common Object Request Broker Architecture
- DCPS         Data-Centric Publish-Subscribe (part of DDS)
- DDS          Data Distribution Service
- DLRL         Data Local Reconstruction Layer (part of DDS)
- IDL          Interface Definition Language

- 1 • UML Unified Modelling Language
- 2 • XML eXtensible Mark-up Language

## 3 **6 Additional Information**

### 4 **6.1 Changes to Adopted OMG Specifications**

5 The proposed submission does not impact the existing CCM specification [[CCM](#)] on the following items:

- 6 • Component Model
- 7 • OMG CIDL Syntax and Semantics
- 8 • CCM Implementation Framework
- 9 • The Container Programming Model
- 10 • Integrating with Enterprise Java Bean
- 11 • Interface Repository MetaModel
- 12 • CIF Metamodel
- 13 • Lightweight CCM profile

#### 14 **6.1.1 Extensions**

15 Nevertheless, for a CCM implementation conformant to this specification, extensions to [[CCM](#)] are provided for:

- 16 • Component Model level to support new keywords **porttype**, **port**, **mirrorport** and **connector**.
- 17 • CIF MetaModel defined in [[UML CCM](#)] with the addition of **ExtendePortType**, **ExtendedPortDef**,  
18 **ConnectorDef**
- 19 • D&C PSM for CCM where 2 classes are added for the support of connectors: **ConnectorPackageDescription** and  
20 **ConnectorImplementationDescriptor**

#### 21 **6.1.2 Changes**

22 The D&C PSM for CCM defined in [[D&C](#)] is modified to integrate

---

**Issue 13955 - Section 6.1.2 It should be **ExtendedPort** and **MirrorPort**, not **InversePort****

---

- 23 | • New CCM port kinds (**ExtendedPort** and **MirrorInversePort**) in the class **CCMComponentPortKind**.
- 24 • A **templateParam** attribute in the class **ComponentPortDescription**

## 1 **6.2 Acknowledgments**

2 The following companies submitted this specification:

- 3 • Thales
- 4 • Real-Time Innovations, Inc.
- 5 • PrismTech Group Ltd
- 6 • Mercury Computer Systems, Inc.

7 The following company supported this specification:

- 8 • Commissariat à l'Energie Atomique (CEA)

# 7 Generic Interaction Support

The proposed Generic Interaction Support includes the definition of *extended ports* and *connectors*. Extended ports can be used at component level to specify the programming contracts that the components need to fulfill in order to interact with other components. Connectors are the entities that can be connected to components via these extended ports, in order to actually realize the interactions.

These extensions fall within the scope of adapting CCM model to specialized application domains, in particular embedded and real-time systems. The lightweight CCM specification has defined a profile to meet embedded equipments. QoS for CCM [QOS4CCM] allows providing non-functional services to components and by this mean allows the use of real-time services plugged into the container. This Generic Interaction Support complements these adaptations with the ability to provide interactions or communication patterns (control of flow, synchronous, asynchronous, shared memory ...) very specific to real-time software.

As for non-functional services, connectors can be platform dependent because they deal with specific communication buses (1553, UDP, TCP, direct calls...) or specific semantics (management of buffers, threads, mutex... inside the fragment). For this reason, they are rather intended to be provided by CCM framework providers or platform providers.

---

**Issue 14201 - Destination module for implied template interfaces**

---

## 7.1 Simple Generic Interaction Support

### 7.1.1 Overview

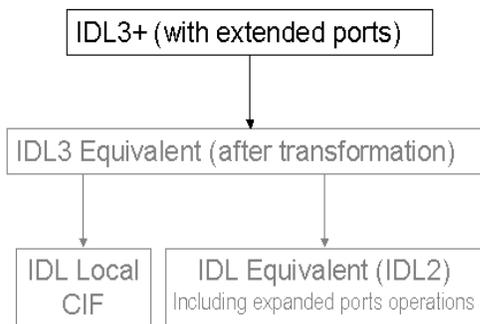

The GIS relies on two constructs: extended ports and connectors. Extensions to IDL3<sup>2</sup> are provided to allow defining and using those constructs.

IDL3+ declarations can be easily translated in plain IDL3. The following figure presents the steps of component definition. Only the first step is new and will be detailed in the following sections:

---

**Issue 13946 - Figure 1 should say IDL3+ instead of Extended IDL3**

---

---

**Figure 1: IDL3+ Transformation**

As resulting IDL3 is exactly as before, the rest of the transformation is kept unchanged.

The transformation from IDL3+ to equivalent IDL3 shall be done by a tool part of a CCM framework implementing the current specification.

---

<sup>2</sup> IDL3 plus its extensions is called IDL3+ in this specification.

## 7.1.2 Extended Ports

An extended port is the mean to represent the programming contract that the components need to deal with, in order to interact according to the corresponding interaction pattern. A programming contract can always be expressed by means of interfaces to call and/or interfaces to be called. Extended ports can be thus subsumed in a group of provided/required interfaces, which can be used/provided. In other words, extended ports are just groups of single CCM ports (facet/**provides** and receptacle/**uses**)<sup>3</sup>.

### 7.1.2.1 IDL3+ Representation

A new keyword **porttype** has been added to IDL3<sup>4</sup> to allow defining extended ports. An extended port definition consists in a list of basic ports (**uses** and/or **provides**).

A second new keyword **port** allows to set a previously defined extended port to a component.

The following is an example of such definitions:

```
//-----  
// IDL3+  
//-----  
  
interface Data_Pusher {  
    void push(in Data dat);  
};  
  
interface FlowControl {  
    void suspend ();  
    void resume();  
    readonly attribute nb_waiting;  
};  
  
// Extended port definition  
porttype Data_ControlledConsumer {  
    provides Data_Pusher consumer;  
    uses FlowControl control;  
};  
  
// Component declaration with that port  
component C1 {  
    port Data_ControlledConsumer p;  
};
```

In the original CCM, existing port kinds are seen as groups of matching basic ports (provided/required interfaces, or events sinks/sources). Similarly, it is needed to define inverses of extended ports (i.e. the ones that will “match” them). To avoid duplicated definitions, the keyword **mirrorport** has been introduced for that purpose. A **mirrorport** results in exactly the same number of simple ports as the **port** of the same **porttype**, except that all the **uses** are turned into **provides** and vice-versa.

### 7.1.2.2 Translation from Extended Ports to Basic Ports

The extensions provided to IDL3 with **porttype**, **port** and **mirrorport** keywords can be directly mapped to usual IDL3 constructs (basic port declarations).

The rules for this transformations are as follows:

- A **provides** in a **port** becomes a **provides** in the equivalent IDL3 declaration of the component;
- A **uses** in a **port** becomes a **uses** in the equivalent IDL3 declaration of the component;

<sup>3</sup> The receptacles correspond to the interfaces that the components will call and the facets, the ones that they will provide to be called.

<sup>4</sup> In this section and the following, the new syntax is just introduced. Formal definition of the new grammar is in section 7.3.

- 1 | • A **provides** in an **mirrorport** becomes a **uses** in the equivalent IDL3 declaration of the component;
- 2 | • A **uses** in a **mirrorport** becomes a **provides** in the equivalent IDL3 declaration of the component
- 3 | • The name of the basic port is the concatenation of the extended port name and the related basic port name of the
- 4 | **porttype**, separated by ' '.

5 | Applying these rules, the previous example will result in the following IDL3 declaration

```
6 | // Resulting IDL3 component definition
7 | component C1 {
8 |     provides Data Pusher p consumer;
9 |     uses FlowControl p control;
10 | };
```

### 11 | 7.1.3 Connectors

12 | Connectors are used to specify an interaction mechanism between components. Connectors can have ports in the same way as

13 | components. They can be composed of simple ports (CCM **provides** and **uses**) or extended ports<sup>5</sup>.

14 | The following figure shows a connector as it can be represented at design level:

**Issue 13956 - Section 7.1.2 Layout of figure 2 and 3 can be improved**

Figure 2: Logical View of a Connector

16 | The connector will concretely be composed of several parts (called *fragments*) that will consist of executors, each in charge

17 | of realizing a part of the interaction. Each fragment will be co-localized to the component using them.

18 | By default, for each port, a fragment (an executor) is produced. If several ports are always co-localized because it

19 | corresponds to the semantic of the connector, their behavior can be provided by the same fragment. This is an implementation

20 | choice for the connector developer.

21 | The following figure shows the connector with its fragments at execution time:

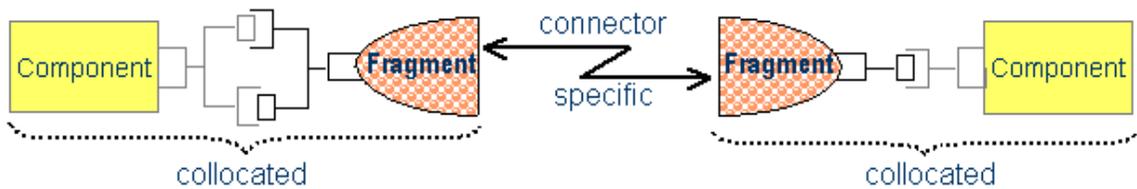

Figure 3: Connector Representation at Execution Time (Fragments)

23 | The communication mechanism between the fragments is connector specific and will be addressed only for DDS support in

24 | this specification.

<sup>5</sup> As generally components will be given extended ports by means of keyword **port**, it is very likely that connectors will use **mirrorport** instead.

1 The connector concept brings another way of seeing CCM: connectors are used to provide interaction (in particular  
2 communication support) between components, and are realized via fragments collocated with the concerned components.  
3 This contrasts with the classical approach, which entails CORBA servants for facets typically provided by code generation  
4 and encapsulating the component executors. An implementation compliant with the present connector specification is not  
5 required to provide CORBA servants and CORBA object references for the component facets.  
6

### 7 **7.1.3.1 IDL3+ Representation**

8 The new IDL3 keyword **connector** allows defining connectors. A connector definition is very similar to a simplified  
9 component's one as a connector is just meant to gather ports (simple or extended). It thus cannot include the **support**  
10 keyword.

11 The following is an example of a connector definition:

```
12 connector Data_Cnx {  
13     mirrorport Data_ControlledConsumer cc;  
14     provides Data_Pusher p;  
15 }
```

### 16 **7.1.3.2 Connector Attributes**

17 A connector can declare attributes in the same way as components. Attributes are declared at connector definition level and  
18 are reflected in each fragment at realization level. For instance in a DDS connector, the topic can be seen as an attribute and  
19 the value of the topic is reflected on each fragment that composes the connector: each fragment of the connector will work on  
20 the same topic.

### 21 **7.1.3.3 Connector Inheritance**

22 A connector can inherit from another connector. It means that the new connector is composed of all the ports and attributes of  
23 the inherited connector in addition to all the ones that are locally defined.

24 The syntax used to declare a connector inheritance is similar to the one used to declare a component inheritance.

### 25 **7.1.3.4 Composite Connectors**

26 A connector (type) can have multiple implementations. As it is the case for components, such an implementation may be an  
27 assembly of other components. For example, an implementation of a local FIFO queue can be provided by a monolithic  
28 implementation, but if this FIFO should enable distribution, an alternative implementation needs to provide multiple  
29 fragments co-localized with the components using them. These fragments can be considered as sub-components within an  
30 assembly (parts within UML composite structures), i.e. an implementation of a connector with multiple fragments is an  
31 assembly implementation. There is no restriction on the level of assembly implementations, for instance a fragment might  
32 itself be realized by an assembly implementation. The advantage of assembly implementations is twofold: first, they enable to  
33 express the fragmented implementation of connectors by concepts already existing in CCM. Second, assembly  
34 implementations enable the composition of connectors, which facilitates the development of new connectors.

35 Consider the example of remote a FIFO. One possible implementation is a FIFO on the consumer's site and a remote access.  
36 The structure of such a remote FIFO implementation is shown in Figure 4. It is composed of two fragments called  
37 respectively SocketClient and FIFO\_Socket\_f\_pull.

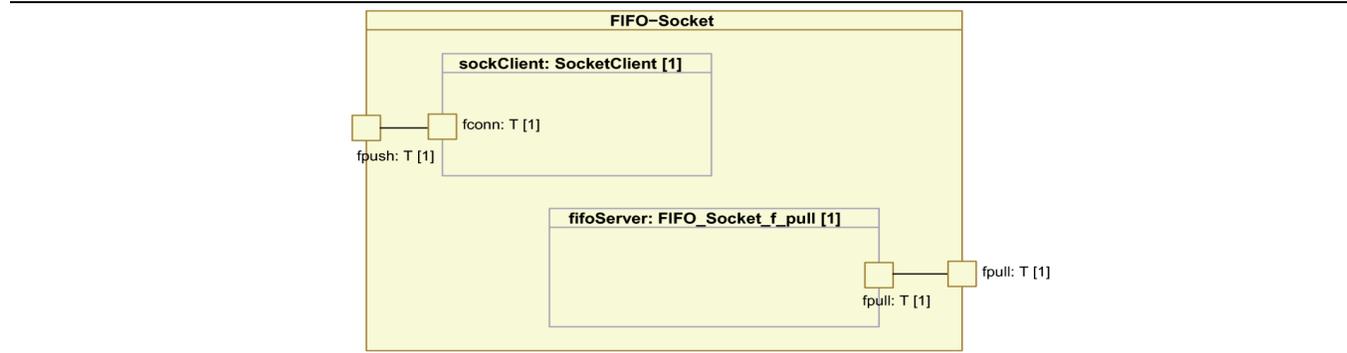

Figure 4: Example of a Distributed FIFO Implementation

Figure 5 shows the detailed implementation of the second fragment (FIFO\_Socket\_f\_pull) which is itself an assembly of 2 fragments: SocketServer and ConnFIFO.

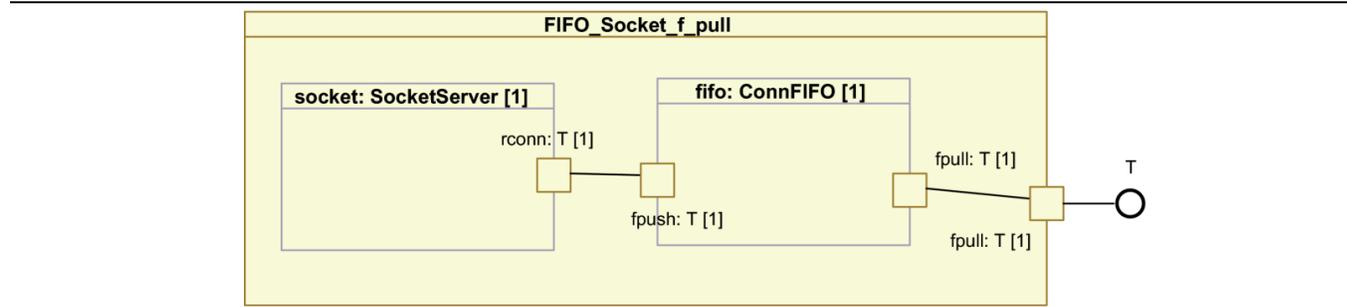

Figure 5: Assembly Implementation of a Connector Fragment

It is thus possible to create new connector implementations by re-assembling existing connectors or fragment implementations. In case of the example, the socket could be replaced by another transport mechanism, for instance an inter process communication.

### 7.1.3.5 Translation to IDL3

The mapping of connector definition to standard IDL3 is trivial: The connector definitions are removed, but the information is used to provide type information at the assembly level. The information shall be described at assembly level to check whether the binding of two ports from a component and a connector, respectively binds identical provided and used types or vice versa.

In a CCM framework providing the support for connector extension, the connector definition in "IDL3+" can be used to generate partly the fragment executors where the connector implementation will be realized (see section 7.6 for more details on connectors realization).

## 7.2 Generic Interaction Support with Templates

As extended ports and connectors are meant to capture interaction logics, their main benefit is obtained if they can be parameterized by types. In the above example, the port `Data_ControlledConsumer` and the connector `Data_Cnx` are only valid for manipulating elements of specific type `Data`. It would be very useful to define generic port type and connector that would provide similar interaction logics to any type of data.

For that purpose, an extension allowing parameterizing definitions of interfaces, ports and connectors has been added to IDL3+. Parametrized definitions can easily be resolved at IDL3+ compilation time.

## 7.2.1 Template Support Overview

The template support is aiming at integrating smoothly in the current IDL specification. It follows therefore the current rules that apply to existing predefined templates (such as sequences): the syntax is very lightweight and anonymous types are not allowed.

The template support allows defining all sensible parameterized interaction support.

Almost any sensible parameterized interaction support will associate at least one port type (itself comprising at least one parametrized interface) with one connector. *The components that integrate the concrete port (resulting from the instantiation of the port type with a given parameter type) and the related concrete connector that provides the mirror port of the same port type need eventually to use/provide exactly the same interface instantiation.*

If the port type on one hand and the connector on the other hand were placed in separate template definitions, this constraint would not be achievable due to anonymous types not being allowed. There is therefore a necessity to offer the mean to group several identically parameterized definitions in the same template scope. Modules are the only IDL grouping constructs. *Therefore the template support is introduced at the module level.*

Note that as parameterizing a module will result in de facto parameterization of all the embedded constructs, this support, offers a lot of possibilities despite its limited impact on the IDL grammar.

## 7.2.2 Template Modules

Using template modules is a two-stepped process:

- First of all the template module is declared.
- Secondly, its instantiation results in a concrete module that is usable as any module.

In addition, a template module can be referenced inside another similarly parameterized module, in order to reuse the related definitions.

### 7.2.2.1 Template Module Declaration

A template module is declared in adding to its declaration a list of comma-separated formal parameters embedded between angular brackets (< and >)

Formal parameters associate a type constraint and the formal parameter name. At instantiation time each formal parameter will be substituted by a concrete value. Only the concrete values that comply with their formal parameter type constraints will be accepted

Type constraints can be:

- typename, meaning that any type will be acceptable;
- some more restricted type designators:
  - interface, meaning all interfaces;
  - valuetype, meaning all valuetype types;
  - eventtype, meaning all eventtypes;
  - struct, meaning all struct types;
  - union, meaning all union types;
  - sequence, meaning all sequence types;
  - array, meaning all array types;

- enum, meaning all enum types;
- a const primitive type, meaning that any constant of the required primitive type will be acceptable;
- a sequence specification, with the constraints that its formal parameters must appear previously in the formal parameters list of the module. In this case, the passed parameter should be a sequence complying with the sequence specification<sup>6</sup>.

The following is a refactoring of the previous example, which has been generalized in order to be usable with any data type.

```

interface FlowControl {
    void suspend ();
    void resume();
    readonly attribute nb_waiting;
};

module Flow <typename T> {
    interface Pusher {
        void push(in T dat);
    };

    // Extended port definition
    porttype ControlledConsumer {
        provides Pusher consumer;
        uses FlowControl control;
    };

    // Connector
    connector Cnx {
        mirrorport ControlledConsumer cc;
        provides Pusher p;
    };
};

```

Note that all constructs that are not T-dependent (here the FlowControl interface) have been put outside the template module to avoid useless duplications. Note also that T-dependency of a construct may be direct, because the formal type is used in the definition (here the Pusher interface) or indirect when the definition makes use of a T-dependent construct (here the ControlledConsumer port type or the Cnx connector).

### **7.2.2.2 Template Module Instantiation**

Once defined a template module has to be explicitly instantiated before being used. Instantiation consist in providing actual values to any formal parameters and a name to the resulting concrete module.

This is done by declaring the concrete module with a new form of the module declaration that inserts, between the keyword module and the module name, the template module instantiation with all values for formal parameters enclosed in angular brackets.

When the module is instantiated, all the embedded constructs are de facto instantiated with the proper parameters values.

<sup>6</sup> This disposal is useful to pass, without duplication, an existing sequence type. Actually, the removal of anonymous types from IDL leads to each similar sequence instantiation be a different type. In case the interaction support needs to manipulate sequence<T> (T being the formal parameter of the template), then there is no means to use the same sequence as the rest of the application but to pass it as a formal parameter.

The following is an example of instantiating the previously defined template module with the data type Data and using the port type in a component.

```
// module instantiation
module Flow<Data> Data Flow;

// component declaration
component C2 {
    port Data Flow::ControlledConsumer p;
};
```

Applying then the IDL3+ to IDL3 translation rules will give the following result:

```
// Resulting IDL3 component definition
component C2 {
    provides Data Flow::Pusher p consumer;
    uses FlowControl p control;
};
```

### 7.3 IDL3+ Grammar

The following description of IDL grammar extensions uses the same syntax notation that is used to describe OMG IDL in CORBA Core, IDL Syntax and Semantics clause. For reference, the following table lists the symbols used in this format and their meaning.

Table 1: IDL EBNF Notation

Symbol	Meaning
<code>::=</code>	Is defined to be
<code> </code>	Alternatively
<code>&lt;text&gt;</code>	Nonterminal
<code>"text"</code>	Literal
<code>*</code> <code>-</code>	The preceding syntactic unit can be repeated zero or more times
<code>±</code>	The preceding syntactic unit can be repeated one or more times
<code>Ω</code>	The enclosed syntactic units are grouped as a single syntactic unit
<code>□</code>	The enclosed syntactic unit is optional—may occur zero or one time

#### 7.3.1 Summary of IDL Grammar Extensions

The following table gathers all the new grammar rules supporting this specification. Those rules aim at completing the existing IDL grammar ("OMG IDL Syntax and Semantics" [IDL]).

The items that are in *italics-blue* are already described in the existing IDL grammar. When they appear here in the right part of a rule, they are considered as terminals. When they appear in the left part of a rule, they are extended by this specification.

Table 2: IDL3+ Grammar Extensions

### 16 | 7.3.3 IDL Extensions for Extended Ports

#### 17 | 7.3.3.1 Port Type Declarations

18 | The following rules allow port type declarations:

19	(2)	<u><code>&lt;porttype dcl&gt; ::= “porttype” &lt;identifier&gt; “{” &lt;port export&gt;+ “}”</code></u>
20	(3)	<u><code>&lt;port export&gt; ::= &lt;provides dcl&gt; “,”</code></u>
21		<u><code>  &lt;uses dcl&gt; “,”</code></u>

22 | A port type declaration is made of:

- 23 | • the **porttype** keyword,
- 24 | • an identifier for the port type name,
- 25 | • the list, of provided and/or used basic ports that constitutes the extended port.

#### 26 | 7.3.3.2 Extended Port Declarations

27 | The following rules allow port declarations

28	(4)	<u><code>&lt;port dcl&gt; ::= {“port”   “mirrorport” } &lt;scoped name&gt; &lt;identifier&gt;</code></u>
29	(5)	<u><code>&lt;component export&gt; ::= &lt;provides dcl&gt; “;”</code></u>
30		<u><code>  &lt;uses dcl&gt; “;”</code></u>
31		<u><code>  &lt;emits dcl&gt; “;”</code></u>
32		<u><code>  &lt;publishes dcl&gt; “;”</code></u>
33		<u><code>  &lt;consumes dcl&gt; “;”</code></u>
34		<u><code>  &lt;port dcl&gt; “;”</code></u>
35		<u><code>  &lt;attr dcl&gt; “;”</code></u>

36 | An extended port declaration comprises:

- 37 | • the **port** or **mirrorport** keyword,
- 38 | • the name of a previously defined port type,
- 39 | • the identifier for the port.

40 | The existing **<component export>** is modified so that such a port declaration can be used to add an extended port to a  
41 | component.

## 7.3.4 IDL Extensions for Connectors

The following rules allow connector declarations:

- (6) `<connector> ::= <connector header> "{" <connector export>* "{"`  
(7) `<connector header> ::= "connector" <identifier> [ <connector inherit spec> ]`  
(8) `<connector inherit spec> ::= ":" <scoped name>`  
(9) `<connector export> ::= <provides dcl> ";;"`  
`| <uses dcl> ";;"`  
`| <port dcl> ";;"`  
`| <attr dcl> ";;"`

A connector is defined by its header and its body.

A connector header comprises:

- the keyword `connector`,
- an identifier for the connector,
- an optional inheritance specification, consisting of a colon and a single scoped name that must denote a previously-defined connector.

A connector body may comprise:

- facet declarations,
- receptacle declarations,
- extended port declarations,
- attribute declarations.

## 7.3.5 IDL Extensions for Template Modules

### 7.3.5.1 Template Module Declarations

The following rules allow template module declarations:

- (10) `<template module> ::= "module" <identifier> "<" <formal parameters> ">" "{" <tpl definition>+ "{"`  
(11) `<formal parameters> ::= <formal parameter> {" , " <formal parameter> }*`  
(12) `<formal parameter> ::= <formal parameter type> <identifier>`  
(13) `<formal parameter type> ::= "typename"`  
`| "interface" | "valuetype" | "eventtype"`  
`| "struct" | "union" | "exception" | "enum" | "sequence"`  
`| "const" <const type>`  
`| <sequence type>`

1 **(14)** <tpl definition> ::= <type dcl> “,”  
2 | <const dcl> “,”  
3 | <except dcl> “,”  
4 | <interface> “,”  
5 | <fixed module> “,”  
6 | <value> “,”  
7 | <type id dcl> “,”  
8 | <type prefix dcl> “,”  
9 | <event> “,”  
10 | <component> “,”  
11 | <home dcl> “,”  
12 | <porttype dcl> “,”  
13 | <connector> “,”  
14 | <template module ref> “,”

15 **(15)** <fixed module> ::= “module” <identifier> “{” <fixed definition>+ “}”

16 **(16)** <fixed definition> ::= <type dcl> “,”  
17 | <const dcl> “,”  
18 | <except dcl> “,”  
19 | <interface> “,”  
20 | <fixed module> “,”  
21 | <value> “,”  
22 | <type id dcl> “,”  
23 | <type prefix dcl> “,”  
24 | <event> “,”  
25 | <component> “,”  
26 | <home dcl> “,”  
27 | <porttype dcl> “,”  
28 | <connector> “,”

29 A template module specification comprises:

- 30 • the **module** keyword,
- 31 • an identifier for the module name,
- 32 • the specification of the template parameters between angular brackets, each of those template parameters consisting  
33 of:
  - 34 • a type classifier, which can be:
    - 35 • **typename**, to indicate that any valid type can be passed as parameter
    - 36 • **interface, valuetype, eventtype, struct, union, exception, enum, sequence**, to indicate that a more  
37 restricted type must be passed as parameter
    - 38 • a constant type, to indicate that a constant of that type must be passed as parameter
    - 39 • a sequence type declaration, to indicate that a compliant sequence type must be passed as parameter (the  
40 formal parameters of that sequence must appear previously in the the module list of formal parameters),
  - 41 • an identifier for the formal parameter,
- 42 • the module body which may contain declarations for port types and/or connectors, other template module references,  
43 as well as all that previously made a classical module body (that last part is named **<fixed module>** in the grammar)<sup>7</sup>.

44 A template module cannot be re-opened (as opposed to a classical one).

<sup>7</sup> Note that this implies that a template module cannot contain another template module.

### 7.3.5.2 Template Module Instantiations

The following rules allow template module instantiations:

(17) <template\_module\_inst> ::= “module” <scoped\_name> “<” <actual\_parameters> “>” <identifier> “;”

(18) <actual\_parameters> ::= <actual\_parameter>{“,” <actual\_parameter>}\*

(19) <actual\_parameter> ::= <type\_spec>  
| <const\_exp>

A module template instantiation consists in providing values to the template parameters and a name to the resulting module. Once instantiated, the module is exactly as a classical module.

The provided values must fit with the parameter specification as described in the previous section. In particular, if the template parameter is of type “sequence type declaration”, then an instantiated compliant sequence must be passed.

### 7.3.5.3 References to a Template Module

The following rules allow referencing template modules:

(20) <template\_module\_ref> ::= “alias” <scoped\_name> “<” <formal\_parameter\_names> “>” <identifier>

(21) <formal\_parameter\_names> ::= <identifier> {“,” <identifier>}\*

An alias directive allows to reference an existing template module inside a a template module definition.

This directive allows to provide an alias name (which can be identical to the template module name) and the list of formal parameters to be used for the referenced module instantiation. Note that that that list must be a subset of the formal parameters of the embedding module.

When the embedding module will be instantiated, then the referenced module will be instantiated in the scope of the embedding one (i.e. as a submodule).

---

**Issue 14024 - keywords that can't be used in other IDL anymore**

---

## 7.3.6 Summary of New IDL Keywords

The following table gathers all new keywords introduced by this specification.

Table 3: New IDL Keywords

<u>alias</u>	<u>connector</u>	<u>mirrorport</u>	<u>port</u>	<u>porttype</u>	<u>typename</u>
--------------	------------------	-------------------	-------------	-----------------	-----------------

## 7.4 Extended Ports

### 7.4.1 Extended Port Definition

Extended ports allow grouping a set of single CCM ports (facet/~~provides~~ and receptacle/~~uses~~), to define a particular semantic. The extended ports are declared in IDL3+ (extended IDL3 with new keywords). A new keyword is introduced to define extended ports (~~porttype~~) and to declare an extended port at component level (~~port~~).

Extended ports can be fixed or parameterized.

#### 7.4.1.1 Fixed Extended Ports

Extended ports can be defined as a list of fixed provided and used IDL interfaces.

1 The following is an example of such a definition:

```
2 //-----  
3 // IDL3+  
4 //-----  
5 //fixed interfaces  
6 interface Data_Pusher {  
7     void push(in Data dat);  
8 };  
9  
10 interface FlowControl {  
11     void suspend();  
12     void resume();  
13     readonly attribute nb_waiting;  
14 };  
15  
16 //extended port definition  
17 porttype Data_ControlledConsumer {  
18     provides Data_Pusher consumer;  
19     uses FlowControl control;  
20 };
```

## 21 7.4.1.2 Parameterized Extended Ports

### 22 7.4.1.2.1 Definition

23 As extended ports are meant to capture interaction logics, their main benefit is obtained if they can be parameterized by  
24 types. In the above example, the **DataControlledConsumer** is only valid for consuming elements of specific type **Data**. It  
25 could be very useful to define a generic port type **ControlledConsumer** that would be usable for any type of sent data.

26 A parameterized definition to ports and interfaces (close to C++ templates, but simplified) is therefore added. This definition  
27 can easily be resolved at IDL compilation time.

28 The following is an example of such a definition::

```
29 //-----  
30 // IDL3+  
31 //-----  
32  
33 // parameterized interface  
34 interface Pusher <typename T> {  
35     void push(in T dat);  
36 };  
37  
38 interface FlowControl {  
39     void suspend();  
40     void resume();  
41     readonly attribute nb_waiting;  
42 };  
43  
44 // extended port definition  
45 porttype ControlledConsumer <typename T> {  
46     provides Pusher <T> consumer;  
47     uses FlowControl control;  
48 };
```

49 The keyword **typename** allows to instantiate the template with any kind of IDL element. Instead of **typename**, the template  
50 can be forced to more specific IDL elements such as: **struct**, **eventtype**, **primitive**, **fixed**, **sequence**, **interface**, **valuetype**.

### 1 | 7.4.1.2.2 Transformation to IDL interfaces

2 | When a port type is defined (whether it is fixed or parameterized), it can be declared as a component port or a connector port  
3 | using new keywords **port** and **mirrorport** that will be specified later on. When a port type is based on a parameterized  
4 | interface, this later needs to be instantiated to obtain the plain IDL interface.

5 | Plain interface definitions will be derived from the parameterized ones, by:-

- 6 | • Applying a simple naming convention to define the interface name: the implied resulting interface will be named by  
7 | concatenating the names of all the parameters, in their declarative order, separated with '\_', followed by the name of  
8 | the template interface, with '\_' as separator;
- 9 | • Replacing the **typename** identifiers by the actual type names in the type declarations;
- 10 | • Replacing the **typename** identifiers placed in the operation names by the actual type names. In this operation the  
11 | character \$ features a concatenation operator in the parameterized definition. This allows the definition of generic port  
12 | types with operation names or interface names depending on parameters. (see example 4)

13 | The following shows the result of such a transformation:-

```
14 | //-----  
15 | // declaration of an extended port  
16 | //-----  
17 | ...  
18 | port ControlledConsumer<Data> p;  
19 | ...  
20 |  
21 | //-----  
22 | // Equivalent IDL  
23 | //-----  
24 |  
25 | // Implied interface definition  
26 | interface Data_Pusher {  
27 | void push (in Data dat);  
28 | };
```

29 | The following is another example (with name construction):-

```
30 | //-----  
31 | // IDL3+  
32 | //-----  
33 |  
34 | // Parameterized interface  
35 | interface EventsPusher <typename T> {  
36 | typedef sequence<T> T$Seq; // construction of a type name  
37 | void push (in T$Seq events);  
38 | void push_$T (in T event); // construction of an operation name  
39 | };
```

```

1 | //-----
2 | // declaration of the extended port
3 | //-----
4 | ...
5 | port_EventsPusher<Data> p;
6 | ...
7 |
8 | //-----
9 | // Equivalent IDL
10 | //-----
11 |
12 | // Implied interface declaration
13 | interface Data_EventsPusher {
14 |     typedef sequence<Data> DataSeq;
15 |     void push (in DataSeq events);
16 |     void push_Data (in Data event);
17 | };

```

18 | The following table shows the way to define a port type:

Table 4: New IDL3 Keyword to Define a Port

<pre> <b>porttype</b> &lt;port_type&gt; ["&lt;" <b>typename</b>   <b>struct</b>   <b>eventtype</b>   <b>primitive</b>   <b>fixed</b>   <b>sequence</b>   <b>interface</b>   <b>valuetype</b> template_id+"] {...}; </pre>	<p>The port type <i>port_type</i> is an extended port and can be parameterized. <b>template_id</b> is replaced by the type used at instantiation.</p>
---	---

19 | The following table shows the way to define parameterized interfaces (template):

Table 5: Syntax to Define a Parameterized Interface

<pre> <b>interface</b> &lt;interface_type&gt; ["&lt;" <b>typename</b>   <b>struct</b>   <b>eventtype</b>   <b>primitive</b>   <b>fixed</b>   <b>sequence</b>   <b>interface</b>   <b>valuetype</b> template_id+"] {...}; </pre>	<p>The interface <i>interface_type</i> is a parameterized interface. <b>template_id</b> is replaced by the type used at instantiation.</p>
---	--

## 20 | 7.4.2 Component Model Extension for Extended Ports

21 | This section deals with the way to define component types using port types

### 22 | 7.4.2.1 Component Port Declaration

23 | The proposed submission introduces a new kind of port at component level, namely an extended port, by means of the new  
24 | IDL3 keyword **port** as shown in the following table:

Table 6: New IDL3 Keyword to Declare an Extended Port As all IDL keywords, they are now reserved and thus may not be used otherwise, unless escaped with a leading underscore.

25 |

26 | ~~FigureFigure~~The new **port** declaration can be parameterized with one or more type elements to instantiate a parameterized  
27 | extended port.

28 | In the original CCM, existing port kinds are seen as basic ports (provided/required interfaces, or events sinks/sources). An  
29 | extended port can be subsumed in a group of provided/required interfaces, which can be used / provided.

30 | To have a similar semantic as basic CCM ports (**uses** and **provides**) for extended ports, it is necessary to introduce a counter  
31 | part to **port** keyword to differentiate if the component (or connector) uses or provides the extended port.

1 To avoid duplicated definitions, the keyword **mirrorport** has been introduced to define inverse of extended ports (as shown in  
 2 the following table). A **mirrorport** results in exactly the same number of simple ports as the port of the same type, except that  
 3 all the **uses** are turned into **provides** and vice versa.

Table 7: New IDL3 Keyword to Declare an Inversed Extended Port

<b>mirrorport</b> <code>&lt;porttype&gt; [{"&lt;"param_type+"&gt;"}] port_name</code>	The port <code>port_name</code> is an inverse port of type <code>porttype</code> <code>{&lt;param_type+&gt;}</code>
--	--

4 Even if the extended ports could be used also directly between components, they are likely to be of primary use for  
 5 connectors as introduced in the next section. Connectors can also only use simple basic CCM ports if sufficient. If a  
 6 component has to be connected to a connector, it has to define basic or extended ports that correspond to those of the  
 7 connector.

8 In the following example, the component C1 makes use of the fixed extended port, while C2 makes use of the parameterized  
 9 one:

```

10 //-----
11 // IDL3+
12 //-----
13
14 component C1 {
15     port Data_ControlledConsumer p; // use of a fixed extended port
16 };
17
18 component C2 {
19     port ControlledConsumer<Data> p; // use of a parameterized extended port
20 };
21 };
```

22 **7.4.2.2 Transformation from IDL3+ to Plain IDL**

23 **7.4.2.2.1 Overview of the Transformation Process**

24 As mentioned above, a set of new keywords has been specified to define extended ports and to declare them in a component  
 25 or connector definition. The resulting declaration with new keywords is called **IDL3+** and has to be transformed in the  
 26 equivalent IDL3 standard definition.

27 The following figure presents the steps of component definitions. Only the first step is new and is detailed in the following  
 28 section:

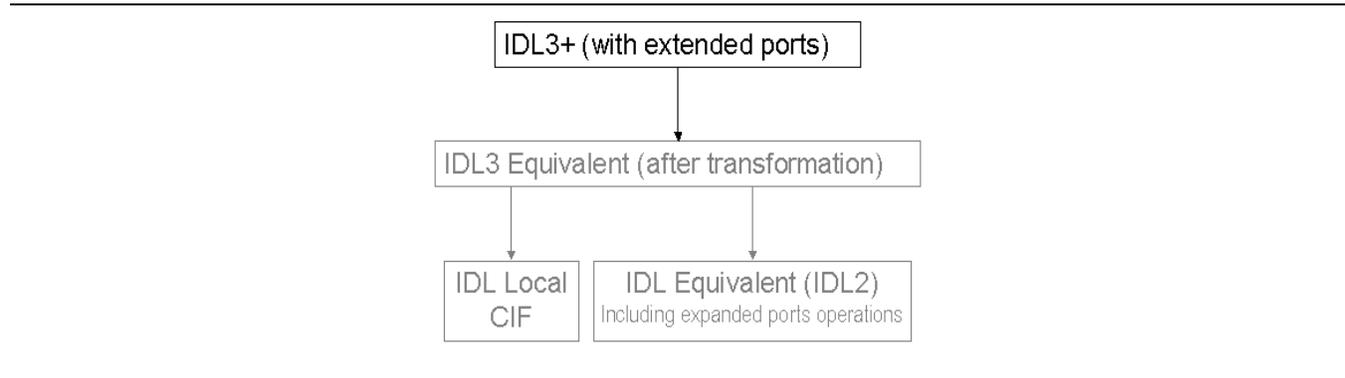

Figure 6: IDL3+ Transformation

30 The transformation from IDL3+ to equivalent IDL3 shall be done by a tool part of the CCM framework implementing the  
 31 current specification.

1 | As resulting IDL3 is exactly as before, the rest of the transformation is kept unchanged.

#### 2 | 7.4.2.2.2 Translation from Extended Ports to Simple Ports

3 | The extensions provided to IDL3 with **porttype**, **port** and **mirrorport** keywords can be directly mapped to usual IDL3  
4 | constructs (basic port declarations):

5 | The rules for this transformations are as follows:

- 6 | • A **provides** in a **port** becomes a **provides** in the equivalent IDL3 declaration of the component;
- 7 | • A **uses** in a **port** becomes a **uses** in the equivalent IDL3 declaration of the component;
- 8 | • A **provides** in an **mirrorport** becomes a **uses** in the equivalent IDL3 declaration of the component;
- 9 | • A **uses** in a **mirrorport** becomes a **provides** in the equivalent IDL3 declaration of the component;
- 10 | • The name of the basic port is the concatenation of the extended port name and the related basic port name of the  
11 | **porttype**, separated by '\_':
- 12 | • If needed, the interface used in the basic port declaration is instantiated from its parameterized version as explained in  
13 | section 7.4.1.2.

14 | The translation for the previous example is as follows:

```
15 | //-----  
16 | //IDL3+  
17 | //-----  
18 |  
19 | //Parameterized interface  
20 | interface Pusher <typename T>{  
21 |     void push(in T dat);  
22 | };  
23 | interface FlowControl {  
24 |     void suspend();  
25 |     void resume();  
26 |     readonly attribute nb_waiting;  
27 | };  
28 |  
29 | //Extended port definition  
30 | porttype ControlledConsumer <typename T> {  
31 |     provides Pusher <T> consumer;  
32 |     uses FlowControl control;  
33 | };  
34 |  
35 | //Component definition  
36 | component C2 {  
37 |     port ControlledConsumer<Data> p; // use of a parameterized extended port  
38 | };  
39 |
```

```

1 | //-----
2 | // IDL3+
3 | //-----
4 |
5 | // Implied interface
6 | interface Data_Pusher {
7 |     void push (in Data dat);
8 | };
9 |
10 | // Component definition
11 | component G2 {
12 |     provides Data_Pusher p_consumer;
13 |     uses FlowControl p_control;
14 | };

```

15 | As the resulting IDL3 is as of now, after this transformation, the CIF (Component Implementation Framework) remains  
16 | unchanged, and nothing is new from the component developer's viewpoint.

17 | At run time, each resulting **provides** will need to be connected to a similar **uses** and each resulting **uses** connected to a  
18 | similar **provides**. Most of the times, even if it is not mandatory, those last **uses** and **provides** will themselves be grouped in  
19 | an extended port, which will be exactly the inverse of the first one. This enforces the need to introduce the **mirrorport**  
20 | keyword.

### 21 | 7.4.2.3 Equivalent IDL (w.r.t Equivalent IDL section in CCM)

22 | This specification does not impact the current CCM specification on the equivalent interfaces that the component developer  
23 | can access. The transformation rules for components are the same. The equivalent IDL interfaces are fully deduced from the  
24 | equivalent IDL3 after extended port transformation. At this stage, the component is defined with standard equivalent CCM  
25 | IDL3 and can be mapped to equivalent IDL in a standard manner (cf. [CCM]).

## 7.4.3 IDL Grammar

The following description of IDL grammar extensions uses the same syntax notation that is used to describe OMG IDL in CORBA Core, IDL Syntax and Semantics clause. For reference, the following table lists the symbols used in this format and their meaning.

Table 8: IDL EBNF Notation

Symbol	Meaning
<b>::=</b>	Is defined to be
<b>†</b>	Alternatively
<b>&lt;text&gt;</b>	Nonterminal
<b>"text"</b>	Literal
<b>*</b>	The preceding syntactic unit can be repeated zero or more times
<b>+</b>	The preceding syntactic unit can be repeated one or more times
<b>{ }</b>	The enclosed syntactic units are grouped as a single syntactic unit
<b>[ ]</b>	The enclosed syntactic unit is optional—may occur zero or one time

### 7.4.3.1 Template Interfaces

The definition of template interface is as follows:

Table 9: IDL Grammar Extensions for Template Interfaces

(22)	<b>&lt;type_classifier&gt; ::= "typename"   "struct"   "eventtype"   "primitive"   "fixed"   "sequence"   "interface"   "valuetype"</b>
(23)	<b>&lt;template_interface&gt; ::= "interface" &lt;identifier&gt; "&lt;" {&lt;type_classifier&gt; &lt;identifier&gt; {"," {&lt;type_classifier&gt; &lt;identifier&gt;}* "}" } {"&lt;export&gt;*"} ["&lt;:"&lt;interface_name&gt; "&lt;"&lt;identifier&gt; {","&lt;identifier&gt;}* "&gt;" {","&lt;interface_name&gt; "&lt;"&lt;identifier&gt; {","&lt;identifier&gt;}* "&gt;}* }</b>

#### 7.4.3.1.1 Type Classifier Definition

The definition of type classifier used to define parameter types for template interfaces or port types is as follows:

(1) **<type\_classifier> ::= "typename" | "struct" | "eventtype" | "primitive" | "fixed" | "sequence" | "interface" | "valuetype"**

#### 7.4.3.1.2 Template Interface Definition

A template interface specification comprises:

- the **interface** keyword;
- an identifier for the interface type name;
- the specification of the template parameters;
- the interface definition;
- optionally, the inheritance from an other template interface.

(2) **<template\_interface> ::= "interface" <identifier> "<" {<type\_classifier> <identifier> {"," {<type\_classifier> <identifier>}\* "}" } {"<export>\*"} ["<:"<interface\_name> "<"<identifier> {","<identifier>}\* ">" {","<interface\_name> "<"<identifier> {","<identifier>}\* ">}\* }**

See section "Interface Declaration" of "OMG IDL Syntax and Semantics" [IDL] for the specification of <identifier> and <export>.

### 7.4.3.2 Port and Port Types

The following description of IDL grammar extensions uses the same syntax notation that is used to describe OMG IDL in CORBA Core, IDL Syntax and Semantics clause.

The extensions to IDL3 grammar consist in the following productions:

Table 10: IDL Grammar Extensions for Ports and Port Types

5	(3) <code>&lt;porttype_dcl&gt; ::= "porttype" &lt;identifier&gt; { " " { &lt;type_classifier&gt; } &lt;identifier&gt; { " " { &lt;type_classifier&gt;</code>
6	<code>&lt;identifier&gt; } * " " } " " { &lt;port_export&gt; + " " }</code>
7	(4) <code>&lt;port_export&gt; ::= &lt;extended_provides_dcl&gt; ";"   &lt;extended_uses_dcl&gt; ";"</code>
8	(5) <code>&lt;extended_provides_dcl&gt; ::= &lt;provides_dcl&gt;   "provides" &lt;generic_template_spec&gt; &lt;identifier&gt;</code>
9	(6) <code>&lt;extended_uses_dcl&gt; ::= &lt;uses_dcl&gt;   "uses" { "multiple" } &lt;generic_template_spec&gt; &lt;identifier&gt;</code>
10	(7) <code>&lt;template_type_spec&gt; ::= &lt;sequence_type&gt;   &lt;string_type&gt;   &lt;wide_string_type&gt;   &lt;fixed_point_type&gt;  </code>
11	<code>&lt;generic_template_spec&gt;</code>
12	(8) <code>&lt;generic_template_spec&gt; ::= &lt;scoped_name&gt; " " { &lt;simple_type_spec&gt; { " " { &lt;simple_type_spec&gt; } * " " }</code>
13	(9) <code>&lt;component_export&gt; ::= &lt;provides_dcl&gt; ";"   &lt;uses_dcl&gt; ";"   &lt;emits_dcl&gt; ";"   &lt;publishes_dcl&gt; ";"  </code>
14	<code>&lt;consumes_dcl&gt; ";"   &lt;attr_dcl&gt; ";"   &lt;extended_port_dcl&gt; ";"</code>
15	(10) <code>&lt;extended_port_dcl&gt; ::= "port" &lt;generic_template_spec&gt; &lt;identifier&gt;   "port" &lt;scoped_name&gt; &lt;identifier&gt;  </code>
16	<code>"mirrorport" &lt;generic_template_spec&gt; &lt;identifier&gt;   "mirrorport" &lt;scoped_name&gt; &lt;identifier&gt;</code>

#### 7.4.3.2.1 Generic Template Specification

The definition of generic templates for interfaces satisfies the following syntax:

- (7) `<template_type_spec> ::= <sequence_type> | <string_type> | <wide_string_type> | <fixed_point_type> | <generic_template_spec>`
- (8) `<generic_template_spec> ::= <scoped_name> " " { <simple_type_spec> { " " { <simple_type_spec> } * " " }`

See section "Type Declaration" of "OMG IDL Syntax and Semantics" [IDL] for the specification of `<sequence_type>`, `<string_type>`, `<wide_string_type>`, `<fixed_point_type>`, `<simple_type_spec>`.

The `<scoped_name>` in `<generic_template_spec>` must be previously defined and introduced either by:

- An interface declaration (`<interface_dcl>`—see Section "Interface Declaration" of "OMG IDL Syntax and Semantics" [IDL]),
- A value declaration (`<value_dcl>`, `<value_box_dcl>` or `<abstract_value_dcl>`—see Section "Value Declaration")
- A type declaration (`<type_dcl>`—see Section "Type Declaration").

Note that exceptions are not considered types in this context.

#### 7.4.3.2.2 Port type definition

A port type definition comprises:

- the keyword **porttype**,
- an identifier for the port type name,
- the template specification if necessary,
- the declaration of basic or parameterized **provides** and **uses** ports

1 | The syntax for port type definition is as follows:

2 | (3) `<porttype_dcl> ::= "porttype" <identifier> { "<" {<type_classifier>} <identifier> {"," {<type_classifier>}  
3 | <identifier>} * ">" } {"<port_export>+ ">"`

4 | (4) `<port_export> ::= <extended_provides_dcl> ";" | <extended_uses_dcl> ";"`

5 | (5) `<extended_provides_dcl> ::= <provides_dcl> | "provides" <generic_template_spec> <identifier>`

6 | (6) `<extended_uses_dcl> ::= <uses_dcl> | "uses" {"multiple"} <generic_template_spec> <identifier>`

7 | See section "Type classifier Definition" of this document for the specification of `<type_classifier_definition>`.

8 | See section "Generic Template Specification" of this document for the specification of `<generic_template_spec>`

9 | See section "Component Body" of "OMG IDL Syntax and Semantics" [IDL] for the definition of `<provides_dcl>`,  
10 | `<uses_dcl>`

### 11 | 7.4.3.2.3 *Extended port Declaration*

12 | An extended port declaration comprises:

- 13 | • the `port` or `mirrorport` keyword,
- 14 | • the name of a previously defined port type (simple or parameterized)
- 15 | • the identifier for the name of the port provided by the component or the connector.

16 | the syntax for extended port type declaration is as follows:

17 | (10) `<extended_port_dcl> ::= "port" <generic_template_spec> <identifier> | "port" <scoped_name> <identifier> |  
18 | "mirrorport" <generic_template_spec> <identifier> | "mirrorport" <scoped_name> <identifier>`

### 19 | 7.4.3.2.4 *Component Declaration Extension*

20 | This syntax complements the defined syntax of section "Component Body" of "OMG IDL Syntax and Semantics" [IDL] for  
21 | the definition of components, by adding the declaration of extended ports.

22 | (9) `<component_export> ::= <provides_dcl> ";" | <uses_dcl> ";" | <emits_dcl> ";" | <publishes_dcl> ";" |  
23 | <consumes_dcl> ";" | <attr_dcl> ";" | <extended_port_dcl> ";"`

## 24 | 7.5 Connector Extensions

25 | This section presents the extensions to CCM component model required to support flexible interactions mechanisms through  
26 | connectors.

### 27 | 7.5.1 Connector Definition

28 | Connectors are used to specify an interaction mechanism between components. Connectors can have ports in the same way as  
29 | components. They can be composed of simple ports (CCM **provides** and **uses**) or extended ports.

30 | The following figure shows a connector as it can be represented at design level:

Figure 7: Logical View of a Connector

The connector is declared using a new IDL3 keyword: **connector**. This keyword is used as the **component** one to define the connector. As for **porttype**, connectors can be fixed or parameterized.

The connector definition cannot include the support keyword because a connector is just meant to gather ports (simple or extended)

The connector defined in IDL3 will concretely be composed of several parts (called *fragments*) that will consist of executors, each in charge of realizing a part of the interaction. By default, for each port, a fragment (an executor) is produced.

If several ports are always co-localized because it corresponds to the semantic of the connector, several ports behavior can be part of the same fragment. Each fragment will be co-localized to the component using them. This is an implementation choice for the connector developer.

The following figure shows the connector with its fragments at execution time:

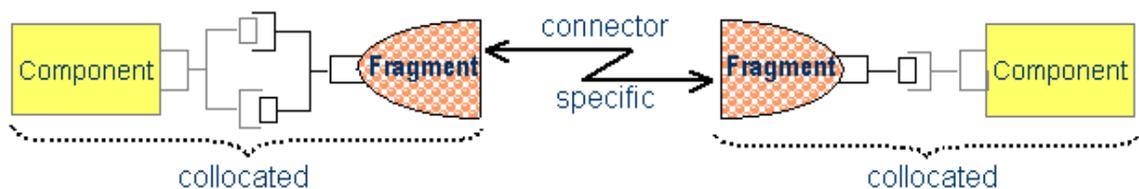

Figure 8: Connector Representation at Execution Time (Fragments)

The communication mechanism between the fragments is connector specific and will be addressed only for DDS support in this specification.

The connector concept brings another way of seeing CCM: connectors are used to provide interaction (in particular communication support) between components, and are realized via fragments collocated with the concerned components. This contrasts with the classical approach, which entails CORBA servants for facets typically provided by code generation and encapsulating the component executors. An implementation compliant with the present connector specification is not required to provide CORBA servants and CORBA object references for the component facets.

The mapping of connector definition to standard IDL3 is trivial: The connector definitions are removed, but the information is used to provide type information at the assembly level. The information shall be described at assembly level to check whether the binding of two ports from a component and a connector, respectively binds identical provided and used types or vice versa.

In a CCM framework providing the support for connector extension, the connector definition in "IDL3+" can be used to generate partly the fragment executors where the connector implementation will be realized (see next section on connector programming).

## 1 | 7.5.1.1 Fixed Connectors

2 | Like components, a connector can declare used and provided ports and interfaces.

3 | The following is an example of connector definition:

```
4 | connector Cnx {  
5 |     mirrorport Data_ControlledConsumer cc;  
6 |     provides Data_Pusher p;  
7 | }
```

## 8 | 7.5.1.2 Parameterized Connectors

### 9 | 7.5.1.2.1 Definition

10 | The above example shows the declaration of a connector with fixed port and extended port; the port types can only be  
11 | **Data\_ControlledConsumer** and **Data\_Pusher**. It could be useful to define a generic connector that could use parameterized  
12 | extended port types.

13 | One interest of connectors is to allow the definition of generic interaction modes following a particular semantic that could be  
14 | adapted easily (by code generation) to concrete user defined interfaces. This is why the notion of template is also used for  
15 | connectors.

16 | The following is an example with parameterized ports::

```
17 | //Connector definition  
18 | connector Cnx <typename T> {  
19 |     port ControlledConsumer<T> cc;  
20 |     mirrorport Pusher<T> p;  
21 | }
```

22 | The keyword **typename** allows to instantiate the template with any kind of IDL element. Instead of **typename**, the template  
23 | can be forced to more specific IDL elements such as: **struct**, **eventtype**, **primitive**, **fixed**, **sequence**, **interface**, **valuetype**.

### 24 | 7.5.1.2.2 Transformation to Concrete Connector

25 | Plain connector definition will be derived from the parameterized ones, by:-

- 26 | • Applying the transformation to the contained ports.
- 27 | • Replacing the **typename** identifiers by the actual type names in the type declarations;

28 | The following table shows the way to declare a connector:

Table 11: New IDL3 Keyword to Define a Connector

<pre><b>connector</b> &lt;connector_type&gt; ["&lt;" <b>typename</b>   <b>struct</b>   <b>eventtype</b>   <b>primitive</b>   <b>fixed</b>   <b>sequence</b>   <b>interface</b>   <b>valuetype</b> template_id+"] {...};</pre>	The connector <code>connector_type</code> is a connector and can be parameterized. <b>template_id</b> is replaced by the type used at instantiation.
---	--

29 | The following example shows how a connector can be instantiated:

```
30 | //Connector instantiation  
31 |  
32 | typedef Cnx<Data> MyCnx;
```

33 | This example when evaluated, will instantiate a connector Cnx with the interfaces Data. It means that this connector  
34 | declaration, after transformation will be similar to the one declared in the fixed connector example.

### 7.5.1.3 Connector Attributes

A connector can declare attributes in the same way as components. Attributes are declared at connector definition level and are reflected in each fragment at realization level. For instance in a DDS connector, the topic can be seen as an attribute and the value of the topic is reflected on each fragment that composes the connector. Each fragment of the connector will work on the same topic.

Table 12: Declaration of Attributes for Connectors

<pre>connector- &lt;connector_type&gt;{ - [readonly] attribute &lt;attr_type&gt; &lt;attr_name&gt;; };</pre>	<p>The connector <i>connector_type</i> exposes attributes named <i>attr_name</i>, of type <i>attr_type</i> and that can be <i>readonly</i>.</p>
--	---

### 7.5.1.4 Connector Inheritance

Conceptually, a connector can inherit from another connector. It means that the new connector is composed of all the ports and attributes of the inherited connector. The syntax to inherit from a connector is similar to the component inheritance:

Table 13: Declaration of Inheritance for Connectors

<pre>connector- &lt;connector_type&gt; : &lt;base_name&gt; {...};</pre>	<p>The connector <i>connector_type</i> inherits from the connector of type <i>base_name</i></p>
---	---

At realization level, the connector to build corresponds to a connector exposing all the inherited ports and attributes, plus its own ports and attributes. All the ports have to be implemented in the fragments composing the connector.

### 7.5.1.5 Composite Connectors

A connector (type) can have multiple implementations. As it is the case for components, such an implementation may be an assembly of other components. For example, an implementation of a local FIFO queue can be provided by a monolithic implementation, but if this FIFO should enable distribution, an alternative implementation needs to provide multiple fragments co-localized with the components using them. These fragments can be considered as sub-components within an assembly (parts within UML composite structures), i.e. an implementation of a connector with multiple fragments is an assembly implementation. There is no restriction on the level of assembly implementations, for instance a fragment might itself be realized by an assembly implementation. The advantage of assembly implementations is two-fold: first, they enable to express the fragmented implementation of connectors by concepts already existing in CCM. Second, assembly implementations enable the composition of connectors, which facilitates the development of new connectors.

Consider the example of remote a FIFO. One possible implementation is a FIFO on the consumer's site and a remote access. The structure of such a remote FIFO implementation is shown in Figure 9. It is composed of two fragments called respectively SocketClient and FIFO\_Socket\_f\_pull.

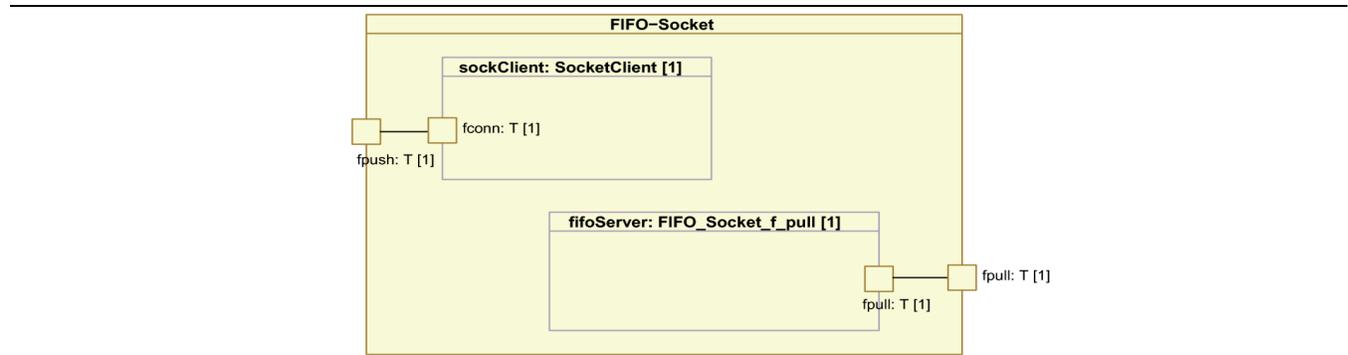

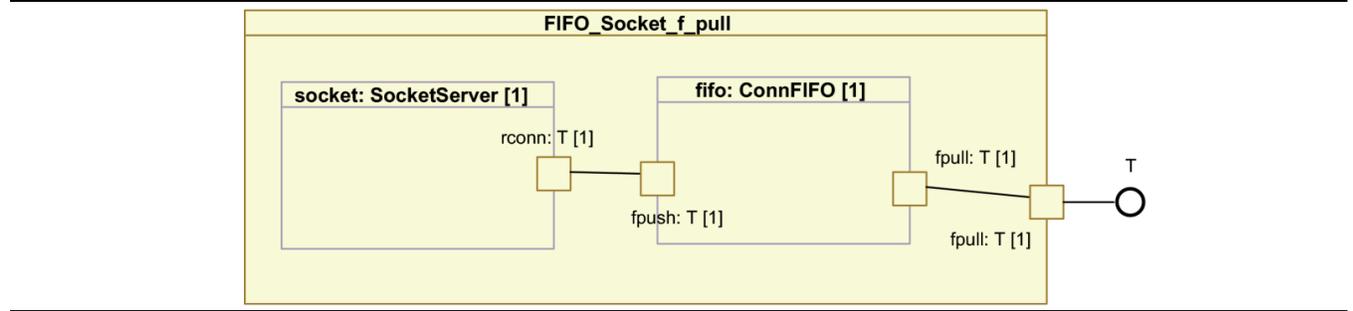

Figure 9: Example of a Distributed FIFO Implementation

Figure 10 shows the detailed implementation of the second fragment (FIFO\_Socket\_f\_pull) which is itself an assembly of 2

1 | fragments: SocketServer and ConnFIFO.

2 | Figure 10: Assembly Implementation of a Connector Fragment

3 | It is thus possible to create new connector implementations by re-assembling existing connectors or fragment  
 4 | implementations. In case of the example, the socket could be replaced by another transport mechanism, for instance an inter  
 5 | process communication.

## 6 | 7.5.2 IDL Grammar for Connectors

7 | A connector is defined by its header and its body.

8 | A connector header comprises:

- 9 | • the keyword **connector**,
- 10 | • an identifier for the name of the connector type,
- 11 | • an optional classifier with its identifier if the connector is a parameterized one (generic connectors)
- 12 | • an optional `<connector_inheritance_spec>`, consisting of a colon and a single `<scoped_name>` that must denote a  
 13 | previously defined connector type.

14 | A connector body comprises:

- 15 | • facet declarations,
- 16 | • receptacle declarations
- 17 | • extended port declarations.

18 | The following description of IDL grammar extensions uses the same syntax notation as to describe OMG IDL in CORBA  
 19 | Core, IDL Syntax and Semantics clause. For reference, the following table lists the symbols used in this format and their  
 20 | meaning.

Table 14: IDL Grammar Extensions for Connectors

21	(11) <code>&lt;connector_inheritance_spec&gt; ::= ":" &lt;scoped_name&gt;</code>
22	(12) <code>&lt;connector_header&gt; ::= "connector" &lt;identifier&gt; [ "&lt;" &lt;type_classifier&gt; &lt;identifier&gt; [ "&lt;" &lt;type_classifier&gt;</code>
23	<code>&lt;identifier&gt; "&gt;"] ] [ &lt;connector_inheritance_spec&gt; ]</code>
24	(13) <code>&lt;connector_body&gt; ::= "{" &lt;connector_export&gt; "}"</code>
25	(14) <code>&lt;connector_export&gt; ::= &lt;provides_dcl&gt; ";"   &lt;uses_dcl&gt; ";"   &lt;extended_port_dcl&gt; ";"   &lt;attr_dcl&gt; ";;"</code>
26	(15) <code>&lt;connector&gt; ::= &lt;connector_header&gt; &lt;connector_body&gt;</code>

27 | See section 7.4.3.1.1 of this document for the specification of `<type_classifier>`.

1 | See section "Attribute Declaration" of "OMG IDL Syntax and Semantics" [IDL] for the definition of <attr  
2 | \_del>.Programming Model for Connectors

## 3 | 7.6 Programming Model for Connectors

4 | This section presents the rules a connector implementer has to follow. This is the counterpart of the CCM component model  
5 | interfaces for connectors and connector ports. As presented in Figure 8, connectors' implementations consist in the  
6 | collaboration of several objects, named fragments or connector executors. They realize the implementation of the connector  
7 | ports and are collocated with the components logically connected to the connector. The proposed programming model is  
8 | oriented towards the provision of objects corresponding to the ports of the connector under consideration. It is therefore  
9 | composed of an API for fragments programming and fragments bootstrapping.

10 | The following are the interfaces necessary to implement a connector's fragment:

```
11 |     module Components {  
12 |         interface CCMObject : Navigation,  
13 |             Receptacles,  
14 |             Events {  
15 |             CCMHome get_ccm_home();  
16 |             void configuration_complete() raises ( InvalidConfiguration );  
17 |             void remove () raises ( RemoveFailure );  
18 |             };  
19 |  
20 |         interface KeylessCCMHome {  
21 |             CCMObject create_component() raises ( CreateFailure );  
22 |             };  
23 |  
24 |         interface CCMHome {  
25 |             void remove_component() raises ( RemoveFailure );  
26 |             };  
27 |  
28 |         interface HomeConfiguration : CCMHome {  
29 |             void set_configuration_values( in ConfigValues config );  
30 |             };  
31 |     };
```

32 | This presents the interfaces that need to be implemented by a connector provider. A **Components::CCMObject** interface has  
33 | to be implemented for each identified fragment of the connector.

34 | This set of interfaces is a subset of the component model coming from the Lightweight CCM specification. All the previous  
35 | methods declared in interfaces have to be defined in the fragment implementation, in order to conform to all D&C  
36 | deployment tools.

37 | In a fragment's implementation, some of these interfaces could be left empty, others are mandatory, among them: **Navigation**,  
38 | **Receptacles** and **KeylessCCMHome**.

---

**Issue 13958 - Section 7.2.3 Line 38-39 starting with "note that events" doesn't read**

---

39 | Note that the Events CCM interface is never used in the connector's executors. The reason is that the connector' fragment  
40 | and the component itself, are only interacting via synchronous calls as they are collocated. The actual interaction semantics  
41 | between components is carried by connector' fragments themselves, as the component and its connector's fragment are  
42 | collocated, they only interact via synchronous calls (a potential asynchronous nature of the actual interaction between  
43 | components would be provided by connector's fragments themselves)

### 44 | 7.6.1 Interface CCMObject

45 | Given a **porttype**, the fragment inheriting **CCMObject** has to implement all necessary operations (**provide\_facet**, **connect**,  
46 | **disconnect**...) inherited from **Components::Navigation** and **Components:: Receptacles** interfaces in accordance with the

1 **porttype.**

## 2 **7.6.2 configuration\_complete**

3 This operation, similarly to components, will be called by the **Application::start** operation [D&C]. This operation is  
4 necessary to activate the handshake between connector fragments at deployment time, after the configuration of all  
5 components and connector fragments.

### 6 **7.6.2.1 get\_ccm\_home**

7 This operation, similarly to components, returns a **CCMHome** reference to the home that manages this component.

### 8 **7.6.2.2 remove**

9 This operation, similarly to components, is used to delete a fragment. Application failures during remove raise the  
10 **RemoveFailure** exception.

## 11 **7.6.3 Interface KeylessCCMHome**

12 This interface merely implements a bootstrapping facility to create connector fragment instances. The same interface is used  
13 by the components. As for components, an entry point allowing the container to create a connector's home instance is defined  
14 and is of type:

```
15     extern "C" { Components::HomeExecutorBase_ptr (*); } // in C++  
16  
17     Components_HomeExecutorBase* (*);           // in C
```

### 18 **7.6.3.1 create\_component**

19 This operation is called to create the connector fragment during deployment.

## 20 **7.6.4 Interface HomeConfiguration**

### 21 **7.6.4.1 Sset\_configuration\_values**

22 As for components, this operation establishes an attribute configuration for the target fragment object, as an instance of  
23 **Components::ConfigValues**. Factory operations on the home of fragment will apply this configurator to newly-created  
24 instances.

## 25 **7.6.5 Equivalent IDL (w.r.t Equivalent IDL section in CCM)**

26 The connector extension does not need to specify equivalent IDL interfaces deduced from ports since only generic operations  
27 inherited from **Navigation** and **Receptacles** are mandatory in the lightweight CCM profile, which is addressed by this  
28 specification.

29 If necessary for a connector, the rules to obtain equivalent interfaces are the same as for a component.

## 30 **7.6.6 Connector Implementation Interfaces**

31 This section explains how can be implemented connector fragments.

32 The CCM provides a standardized Component Implementation Framework (CIF) defining the programming model for  
33 constructing component implementations.

1 The connector implementation (implementation of several fragments) is specific to the semantic it defines; it can be  
2 dependant of the underlying platform and is connector provider specific. For that reason, there is no need to standardize a  
3 counter part of the CIF for connectors.

4 As explained before, the implementation of a fragment inherits the **Components::CCMObject** interface and shall implements  
5 the specified operations of **Navigation, Receptacles**. This is mandatory to provide a connector that can be deployed and  
6 configured with lwCCM deployment framework (compliant to D&C specification [D&C]). This implementation corresponds  
7 to a classical implementation of IDL interfaces using the standard language mapping.

8 As for components, the skeleton of connector fragments can be partly generated taking into account the transformation rules  
9 defined in the connector definition. This is fully the responsibility of the connector framework provider.

## 10 **7.7 Connector Deployment and Configuration**

11 This section introduces all the modifications to the OMG D&C specification considered as necessary in order to deal with the  
12 packaging and deployment of connectors. The extensions are to be added in the PSM for CCM part of D&C reference in the  
13 following specification: [CCM]

14 Remark: this section and the following are based on the D&C specification [D&C]; all conventions defined in this  
15 specification are applicable:

- 16 • In particular, standard attributes (e.g. label) have the semantics defined in the D&C specification.
- 17 • All classes that are not explicitly defined in this document are taken from the specification
- 18 • In the UML diagrams, when no multiplicity is indicated on an association end, the multiplicity is one.

19 Note that extended ports and connectors (considered as CCM extensions) defined in the previous sections, as an extension of  
20 IDL3 have no impact on the D&C PIM; it will only impact the PSM for CCM level [CCM].

### 21 **7.7.1 Integration of Connectors in D&C**

22 As said before, the objective of this specification is to provide new interaction modes for component-based applications. To  
23 achieve this goal, it shall not add complexity for the assembly of components. For this reason, the connectors in a  
24 component-based application design shall be seen as an interaction element that links 2 components and not as a new  
25 functional entity that will imply multiplication of connections at assembly level. Nevertheless it implies some modifications  
26 to the D&C Component Data Model at assembly level where connections will include connector information.

27 On the contrary, at Execution Data Model level, since the deployment plan aims to be [automatically] produced at planning  
28 phase by tools, and since it is a *flattened assembly*, the connector defined in the connection elements of the assembly will  
29 appear as artifacts that have to be deployed by the deployment tools. This implies that the fragment instances (artifacts) are  
30 described in the deployment plan with their configuration values; and that connections between components and their related  
31 fragment are basic connections (facet / receptacles).

### 32 **7.7.2 Component Data Model**

33 A connector is an entity very similar to a component. It is packaged, deployed and owns implementation(s), as well as  
34 interfaces, etc. Therefore, it would not have been relevant to define a completely new data model for connectors.

#### 35 **7.7.2.1 Connector Description**

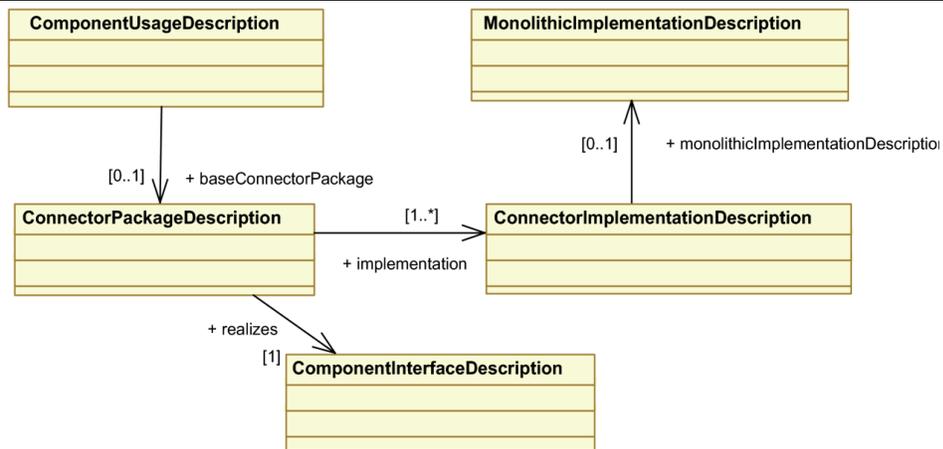

---

**Issue 13959 - Section 7.2.4.2.1**

---

36 Connectors may be packaged in the same way components are, thus most of the elements defined in the component data  
37 model are relevant in the case of connectors. However, component packages and connector packages shall be distinguishable;

- 1 therefore a **ConnectorPackageDescription** class is defined.
- 2 Like a component package, a connector package owns descriptive information (interface description) and one or more  
3 implementation(s).
- 4 As far as the interface description is concerned, no differences exists between components and connectors, thus the  
5 **ComponentInterfaceDescription** class is used for connectors as well and is extended at PSM level to integrate extended port  
6 specificities.
- 7 In the following, all diagrams of the component data model impacted by the above statements are displayed.
- 8 The following figure displays the additions<sup>8</sup> that are to be made to the Component Data Model at PSM for CCM level.
- 9 | Actually, two classes are added: **ConnectorPackage-Description**<sup>9</sup> and **ConnectorImplementationDescription**.

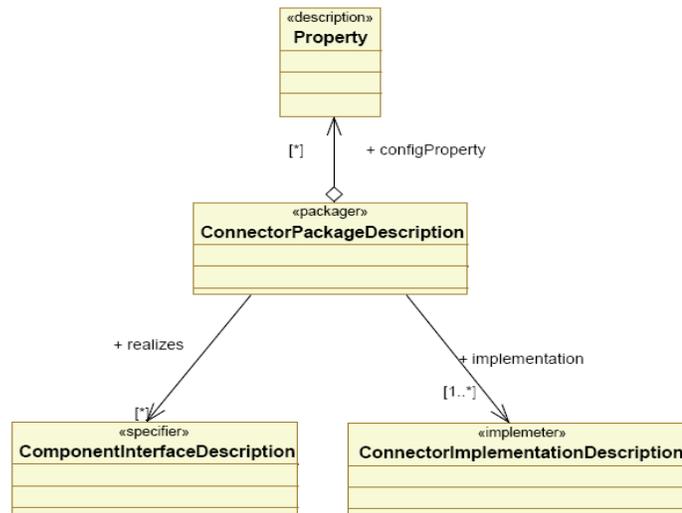

10

Figure 11: Revised component data model overview

- 11 The two following figures give a detailed description of **ConnectorPackageDescription** and  
12 **ConnectorImplementationDescription** classes.

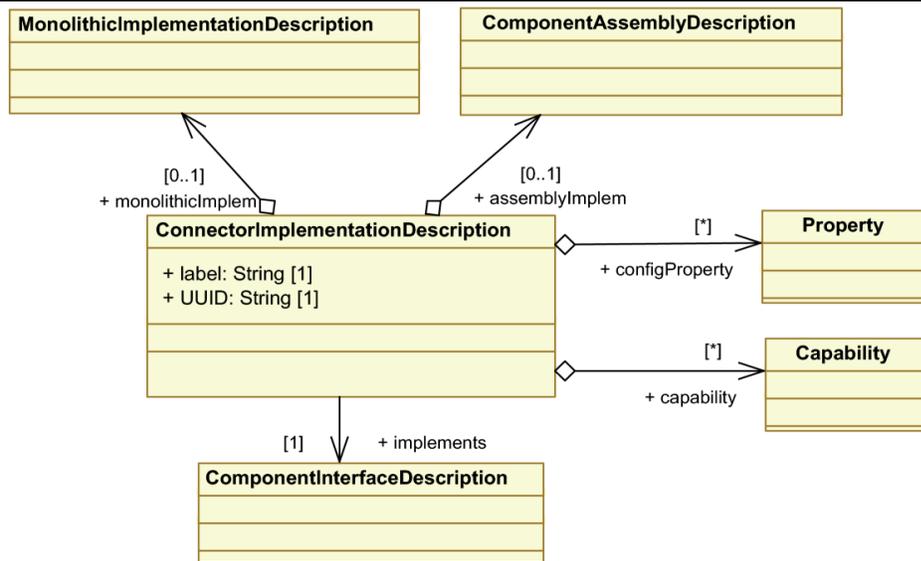

<sup>8</sup> Note that this diagram displays only the two classes that have to be added, along with their relations to already existing classes. All the classes originally defined in the specification are, even if not represented here, left intact, as well as their relations.

<sup>9</sup> The association between **ComponentUsageDescription** and **ConnectorPackageConfiguration** is in mutual exclusion with those defined in the initial component data model between **ComponentUsageDescription** and **ComponentPackageDescription**.

1

Figure 12: ConnectorPackageDescription Class

2

Figure 13: ConnectorImplementationDescription Class

### 3 7.7.2.2 ConnectorPackageDescription

4 A **ConnectorPackageDescription** describes multiple alternative implementations of the same connector. It references the  
 5 interface description for the connector and contains a number of configuration properties to configure the running connector  
 6 (which may override implementation-defined properties and which may be overridden by a **PackageConfiguration**). These  
 7 configuration properties enable the packager to define default values for a connector's properties regardless of which  
 8 implementation for that component is chosen at deployment (planning) time.

### 9 7.7.2.3 ConnectorImplementationDescription

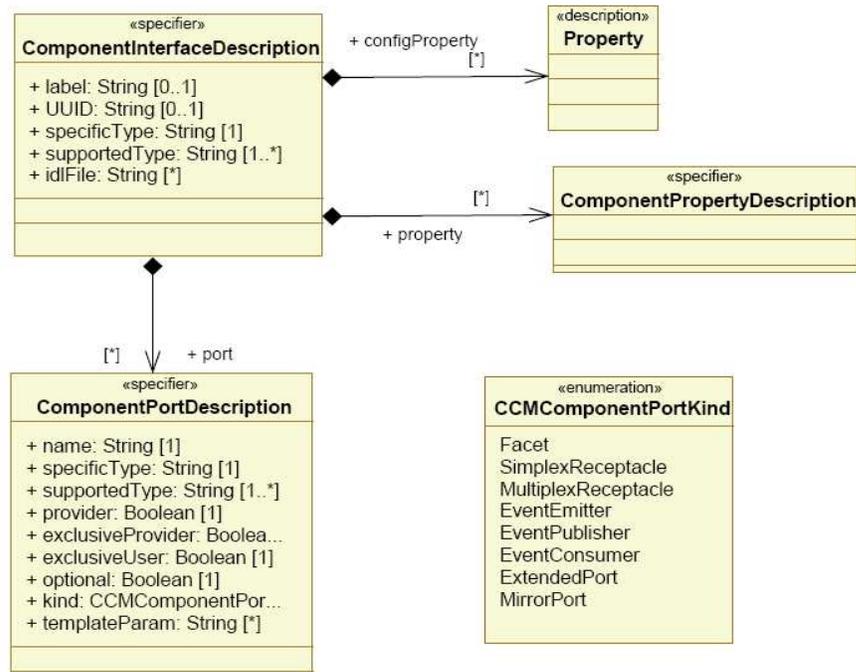

10 A **ConnectorImplementationDescription** describes a specific implementation of a connector. This implementation can be  
 11 only monolithic. The **ConnectorImplementationDescription** may contain configuration properties that are used to configure  
 12 each connector fragments instance ("default values"). Implementations may be tagged with user-defined capabilities.  
 13 Administrators can then select among implementations using selection requirements in a **PackageConfiguration**.

1 The **ComponentInterfaceDescription** class is used to describe components and connectors. This description contains  
2 information on the ports of components and connectors.

3 **ComponentPortDescription** class shall be extended to support the extended ports. As explained in previous sections,  
4 extended ports are defined at least by their specific types (**specificType** member of **ComponentPortDescription**) but they  
5 can also be parameterized by several template parameters. The class is therefore extended with a **templateParam** member.  
6 The kind of port shall also support extended ports and inverse ports. The **CCMPortKind** enumeration is extended with two  
7 values: **ExtendedPort**, **MirrorPort** .

#### 8 7.7.2.4 ComponentInterfaceDescription

9 The added **ComponentPortDescription::templateParam** (String [0..\*]) contains all the template parameters types needed to  
10 parameterize the port (if extended). This member is null if the port is simple or if it is an extended port without template. If  
11 **templateParam** contains values, the **CCMComponentPortKind** attribute shall be **ExtendedPort** or **MirrorPort**

12 Figure 14: Support for Extended Ports

13 The connector description will be part of .ccd files.

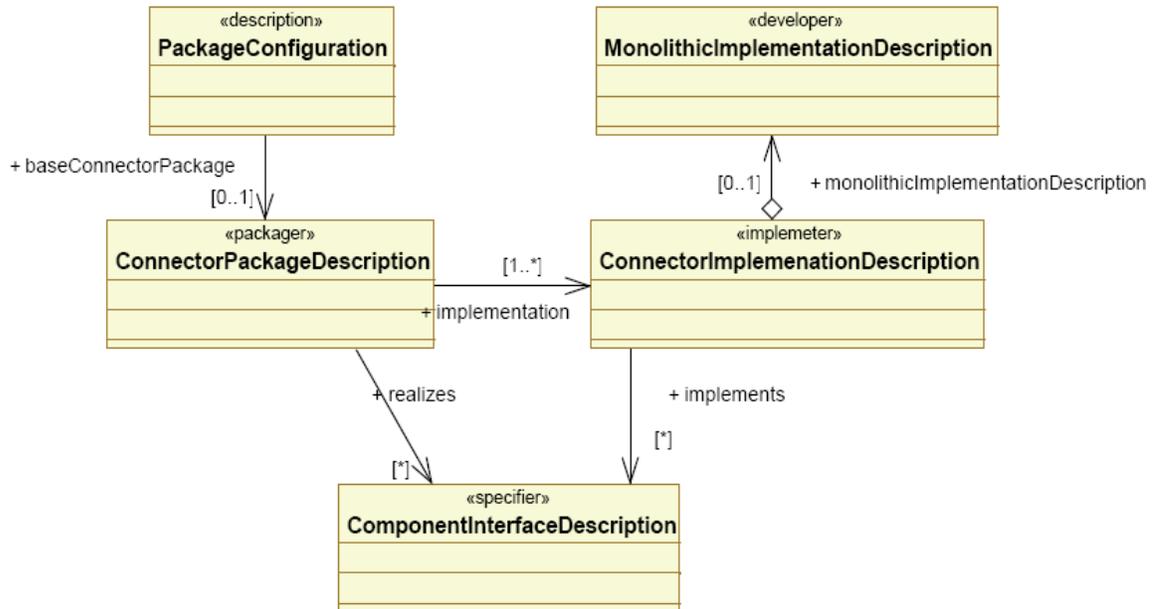

#### 14 7.7.2.5 Component Assembly with Connectors

15 At D&C assembly level, using a connector shall result in a set of connections between components and shall not appear as a  
16 new component instance in the assembly.

17 In the D&C specification, the **ComponentAssemblyDescription** element contains information about subcomponent  
18 instances (**SubcomponentInstantiationDescription**), connections among ports (**AssemblyConnectionDescription**), and  
19 about the mapping of the assembly's properties (i.e., of the component that the assembly is implementing) to properties of its  
20 subcomponents.

21 Connectors at assembly level are considered as particular connections. It means that the **AssemblyConnectionDescription**  
22 need to be extended to support connector descriptions. At PSM for CCM level, the following extensions are specified:

- 1 The **AssemblyConnectionDescription** can be realized by a connector. Therefore, this class provides a direct association  
 2 with **ConnectorPackageDescription**. The principle is similar to **SubComponentInstantiationDescription** that (by  
 3 inheritance of **ComponentUsageDescription**) references **ComponentPackageDescription** itself referencing the connector  
 4 definition (**ComponentInterfaceDescription**).
- 5 The association is 0..1. If the cardinality is 0 the connection is a basic CCM connection (facet → receptacle and events), if it  
 6 is 1 the connection is implemented by a connector.

7  
 Figure 15: AssemblyConnectionDescription Extension

### 8 7.7.3 Execution Data Model

9 At the Execution Data Model level, the deployment plan is produced from the assembly description and corresponds to the  
 10 assembly fully flattened. All executable artifacts are part of the deployment plan.

11 Each connector fragment is described as artifacts (**ArtefactDeploymentDescription**), implementations  
 12 (**MonolithicDeploymentDescription**), instances (**InstanceDeploymentDescriptions**). By definition a connector  
 13 implementation is the result of its fragment implementations. Each fragment can be deployed on different a target, that's why  
 14 at the execution model level, fragments are manipulated while at Component Data Model, connectors are manipulated.

15 The transformation from assembly level (designed in a modeling tool) to the resulting deployment plan can be easily  
 16 generated since all parameterized typed are resolved when the assembly tool connects components with a connector. The  
 17 resulting simple ports of components and connector fragments will be the endpoints to connect at deployment time.

18 This way of proceeding implies a very small impact on the existing deployment frameworks since they will deal with the  
 19 same entities (artifacts, implementations, instances and connections). Nevertheless few extensions are necessary to allow the  
 20 instantiation of connector fragments and their configuration.

#### 21 7.7.3.1 Compliance with Entry Points

22 This section refers to the section 10.6.1 of D&C [D&C] regarding the CCM entry points.

- 1 If the instance to be deployed is a connector, then the name of the execution parameter shall be "**home factory**"
- 2 The parameter is of type String, and its name is the name of an entry point that has no parameters and that returns a pointer of
- 3 type **Connectors::HomeExecutorComponents:: HomeExecutorBase**.
- 4 Thanks to this object, the deployment tool will call the **create\_component()** operation on the **KeylessCCMHome** to
- 5 instantiate a connector fragment.

## 6 7.7.4 Connector Configuration

- 7 The configuration of port type at assembly level produces the needed configuration values at deployment time.

---

**Issue 13960 - Section 7.2.4.4 Line 3-4 doesn't read**

---

8 ~~Each fragment of a connector providing an implementation of an extended port, have to be linked to its dual one, the mirror-~~  
 9 ~~port. In some cases, to be configured and linked together, fragment to configure have to query some data from the dual one.~~  
 10 ~~Taken into account that, the two fragments can be installed on different nodes, the process of configuration has to be~~  
 11 ~~remote. All fragments of a given connector are in relation and have to be configured consistently. In some cases, this could~~  
 12 ~~require them to share configuration information that cannot be set statically. This dynamic initialization, if required, is~~  
 13 ~~connector implementation-specific and thus not specified. However it has to be completed by the end of the~~  
 14 ~~'configuration complete' phase of CCM deployment.~~

- 15 To configure the fragments the **Components::HomeConfiguration** IDL interface could be used. The method
- 16 **set\_configuration\_values** is called in order to set the needed **ConfigValues** for the connector.

- 17 If two fragments need to exchange some configuration data (e.g. CORBA reference) the naming service could be used.

- 18 The configuration data are specified in the Component Deployment Plan file. Following is an example that shows how to
- 19 configure fragments at deployment plan level.

```

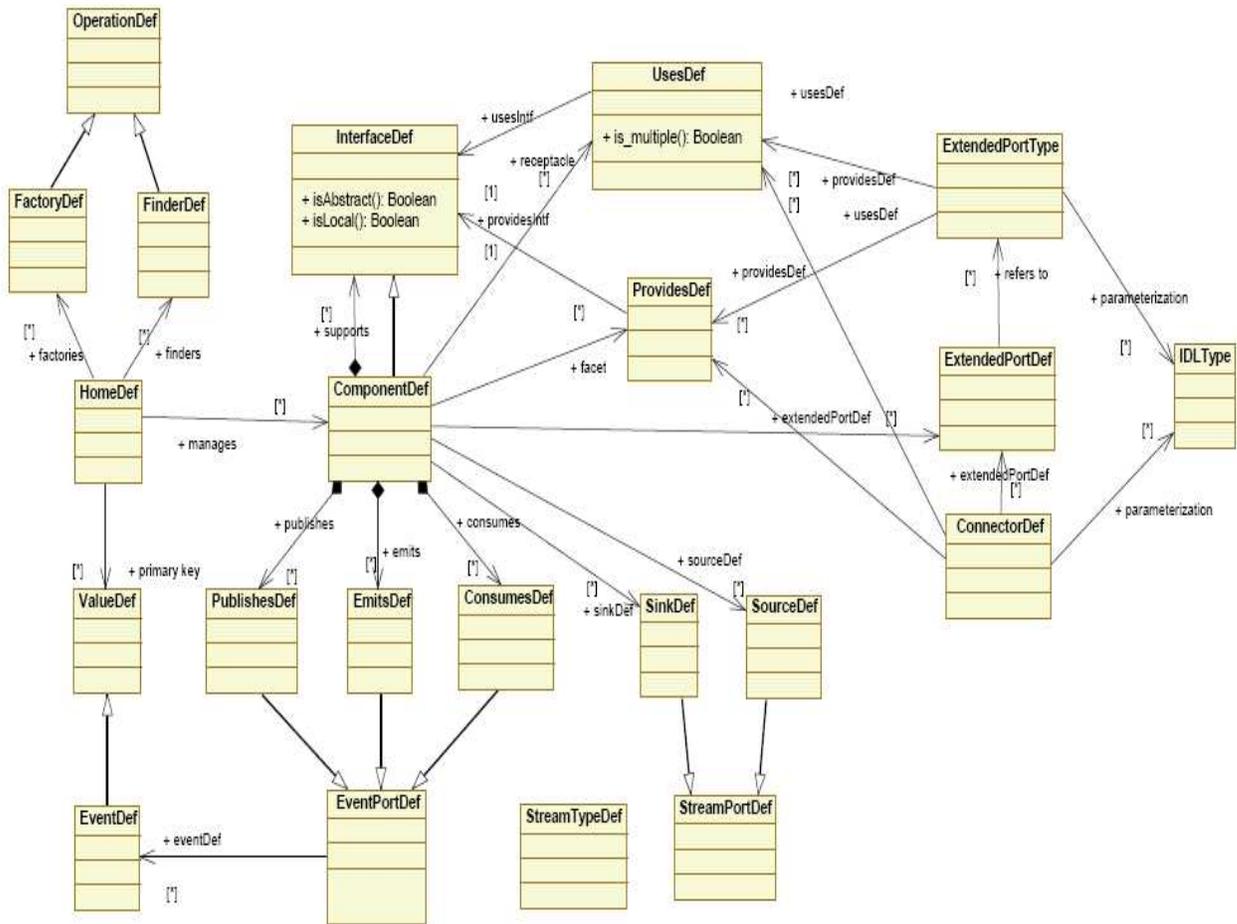

20 <!-- ***** -->
21 <!-- ***** INSTANCES ***** -->
22 <!-- ***** -->
23 <!-- Instance for fragment_instance_1 -->
24 <instance id="fragment_instance_1">
25     <name>fragment_instance_1</name>
26     <node>node1</node>
27     <implementation ref="fragment_impl_1"/>
28     <configProperty>
29         <name>mcast_addr</name>
30         <type>string</type>
31         <value>224.1.1.1</value>
32     </configProperty>
33     <configProperty>
34         <name>mcast_port</name>
35         <type>unsigned short</type>
36         <value>31337</value>
37     </configProperty>
38     <configProperty>
39         <name>msg_size</name>
40         <type>unsigned long</type>
41         <value>50</value>
42     </configProperty>
43 </instance>

```

## 44 7.7.5 CCM Meta-model Extension to support Generic Interactions

- 45 In this section, the basic concepts of the component model are summarized, based on the CCM meta-model [\[UML CCM\]](#).
- 46 Central to it is the notion of Component definition (**ComponentDef**). It corresponds to the specification of a new component
- 47 type, providing, using, and supporting possibly several interfaces, as well as consuming, emitting or publishing event types.

- 1 For configuration issues, attributes can be used as part of component definitions
- 2 This part is based on the specification [UML\_CCM] and extends it with new meta classes.
- 3 As an extension, the specification introduces the **ExtendedPortDef** as well as **ExtendedPortType** in the meta-model in order
- 4 to allow definition of custom types of ports, the primary motivation being the reification at component level of interactions,
- 5 which will be supported by the Connector concept

7 Figure 16: Component Meta-Model – With Extended Ports and Connectors

- 8 **ExtendedPortType** are aggregation of zero or several provisions or needs of interfaces.
- 9 A matching relation for **ExtendedPortType** is defined as follows: two such types are compatible when they present one by
- 10 one compatible **UsesDef** and **ProvidesDef**.

**Issue 13961 - Section 7.2.4.5 this seems to lack a figure, line 7 ends with "extrat below" but nothing is below line 7**

11 In addition to the **ExtendedPortDef** and **ExtendedPortType**, the concept of **connector** is introduced, represented in the  
 12 meta-model extract below: Finally, **ConnectorDef** is a new construct of the Component meta-model allowing modeling of  
 13 connectors.

14 All those extensions are represented on figure 16.

# 8 DDS-DCPS Application

This section instantiates the Generic Interaction Support described in the previous section, in order to define ports and connectors for DDS-DCPS. This section assumes an a-priori knowledge of DDS specification, at least of its DCPS part.

## 8.1 Introduction

### 8.1.1 Rationale for DDS Extended Ports and Connectors Definition

DDS is a very versatile middleware. It allows to accommodate almost any conceivable flavor of data-centric publish/subscribe communication and therefore presents a very rich API and a very complete set of underlying behaviors and QoS policies. The counterpart of this richness is a certain complexity which may lead to errors or malfunctions due to mistaken uses.

Therefore, purpose of "DDS for lightweight CCM" should be twofold:

- Easing the deployment of applications made of components interacting through DDS by placing DDS configuration in the general component scheme (where configuration is carefully kept separated from the pure application code)
- Providing to the components' author an easier access to DDS, by defining ready-to-use ports that would hide as much as possible DDS complexity.

However, ease of use should not come with too many restrictions that would compromise usefulness. In addition, as DDS is very versatile, defining a single couple of write and read ports that could accommodate simply all potential DDS usages seems unrealistic.

The process used to identify relevant DDS ports and connectors has been as follows:

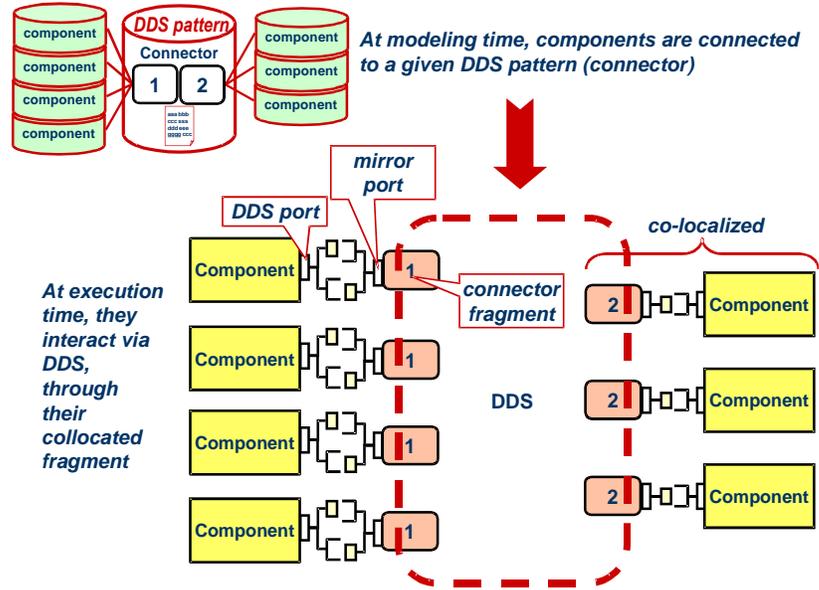

- A large variety of DDS use patterns have been analyzed;
- Then for each pattern, the roles<sup>1</sup> have been identified and characterized in terms of:
  - Associated DDS entities,
  - Related QoS settings and
  - Programming contracts;
- All the identified programming contracts have been then analyzed and grouped to define DDS ports (*each resulting programming contract corresponds to one DDS port*);
- *The most common DDS use patterns have been then identified as connectors*, with their related DDS ports, their underlying DDS entities and associated QoS settings.

Even if these principles are general enough to be applicable to DCPS and DLRL uses of DDS, their actual realization results in extended ports and connectors that are specific to DCPS or DLRL.

### 8.1.2 From Connector-Oriented Modeling to Connectionless Deployment

It should be well understood that, even if at modeling levels DDS-enabled components are said 'connected' to a DDS-connector through their DDS-ports, that does not mean at all that they are physically connected (DDS is connectionless by nature). The following picture illustrates this change of paradigm from components connected to a DDS pattern at modeling time (in green) to components interacting via DDS through DDS ports to fulfill this DDS pattern at execution time (in

1 yellow).

2

Figure 17: From Modeling to Actual Deployment

## 3 8.2 DDS-DCPS Extended Ports

### 4 8.2.1 Design Rules

#### 5 8.2.1.1 Parameterization

**Issue 14213 - Sequence typedef leads to multiple sequences**

6 DDS-DCPS ports and connectors will be grouped in a module, itself parameterized by the data type and a sequence type of  
7 that data type.

- 8 • Grouping the definitions for port types and connectors in the same module allows that they share the same concrete  
9 interface when eventually instantiated.
- 10 • Passing that second parameter may seem redundant but it is the only way to allow sharing the sequence definition  
11 with the rest of the application<sup>10</sup>.

12 To avoid useless duplications when instantiated, this template module will only contain the constructs that depend on the  
13 data-type. It will be included in a more general module that will also contain all the constructs that do not depend on the data-  
14 type.-

15 Note: The following ports selected to be normative as fitting most DDS use patterns, are all parameterized by only one data  
16 type. However, as the Generic Interaction support allows to define new port types, nothing prevents users to define more  
17 specific ports that would be parameterized by several data types.

#### 18 8.2.1.2 Basic Ports Definition

19 DDS-DCPS ports, as extended ports, will be made of several basic ports (**uses** and/or **provides**) with their defined  
20 interfaces.

<sup>10</sup> Otherwise, the sequence created by this definition would be a type different (even if actually identical) from the one used by the application (created by the application or by DDS), which would lead to continual copies between one and the other.

1 The rationale to group operations a single interface (thus one basic port), or on the contrary, to split them in different  
2 interfaces (thus several basic ports) is as follows:

- 3 • Different interaction directions (i.e. whether the component is a caller or a callee) result in different interfaces
- 4 • Each interface is focused on a precise area of functionality (such as data access, status access...)

5 All those interfaces could be then considered as building blocks for DDS-DCPS extended ports.

### 6 **8.2.1.3 Interface Design**

7 For simplicity reasons, it has been chosen not only to keep ~~only~~ the strictly needed operations, but also to simplify their  
8 parameters as much as possible. in particular:

- 9 • Information that comes with the read data samples have been simplified to what is most commonly used.
- 10 • Data access parameters, when they are likely to be shared by all the access of a given port (e.g. a query for read) are  
11 expressed by means of basic port interface attributes. Those attributes can be seen configurations for the ports

12 Errors are reported by means of exceptions.

### 13 **8.2.1.4 Simplicity versus Richness Trade-off**

14 The goal of this specification is not is not to prevent the advanced user to make use of advanced DDS features if needed. In  
15 return, complicating the mainstream port interfaces should be avoided. This is the reason why, each DDS port contains a  
16 extra basic port to access directly to the more scoped underlying DDS entity (e.g. the **DataWriter** if it is a port for writing). If  
17 needed, all the involved DDS entities can be retrieved by with this starting point.

18 Note: The proposed DDS-DCPS ports are of large potential usage. However as the Generic Interaction support allows to  
19 define new port types, nothing prevents users to define their own DDS ports to fulfill more specific use patterns.

## 20 **8.2.2 Normative DDS-DCPS Ports**

21 This section lists the normative DDS extended ports. It starts with the list of proposed interfaces for basic ports and then  
22 assemble them to make the DDS ports.

---

### Issue 14213 - Sequence typedef leads to multiple sequences

---

23 All those constructs are included in the Typed template sub-module of the CCM DDS module, as follows:

```
24 module CCM DDS {  
25     // Non-typed definitions  
26     ...  
27     module Typed <typename T, sequence<T> TSeq> {  
28         // Typed definitions  
29         ...  
30     };  
31 }
```

32 In the following sections are thus listed extracts from the template module CCM DDS::Typed<typename T, sequence<T>  
33 TSeq>.

34 The whole consolidated IDL is listed in Annex A: IDL3+ of DDS-DCPS Ports and Connectors.

---

### Issue 14209 - Dds4ccm and includes

---

35 This IDL file is named "ccm dds.idl".

## 1 8.2.2.1 DDS-DCPS Basic Port Interfaces

### 2 8.2.2.1.1 Data Access – Publishing Side

3 ~~Several~~Two interfaces allow to write DDS data:

- 4 • A **Writer**, allows ~~to publish~~publication of data on a given topic without paying any attention to the instance lifecycle.  
5 Therefore it just allows writing values of the related data type.
- 6 • An **Updater** allows ~~to publish~~publication of data on a given topic when you do care of instance lifecycle. Therefore it  
7 allows creating, updating and deleting instances of the related data type. It can be configured to actually check the  
8 lifecycle globally or ~~not just locally~~. A **MultiWriter** is a **Writer** which doesn't act on instances one by one (as a **Writer**  
9 does), but per group (sequences). In addition, it may be configured so that each of its actions is 'coherent' as far DDS  
10 is concerned (i.e. embedded in a couple of begin\_coherent\_updates, end\_coherent\_updates)
- 11 • A **MultiUpdater** is an **Updater** which doesn't act non on instances one by one (as an **Updater** does), but per group  
12 (sequences). In addition, it may be configured so that each of its actions is 'coherent' as far DDS is concerned (i.e.  
13 embedded in a couple of begin\_coherent\_updates, end\_coherent\_updates)
- 14 •

15 The following IDL declarations of those related interfaces are followed by explanations when needed:

---

**Issue 14567 - Updater and instance handle**

---

#### 16 InstanceHandleManager

```
17 abstract interface InstanceHandleManager {  
18     DDS::InstanceHandle t register_instance (in T datum)  
19         raises (InternalError);  
20     void unregister_instance (in T datum , in DDS::InstanceHandle t instance_handle)  
21         raises (InternalError);  
22 };
```

23 This interface gathers the two operations that allows manipulating DDS instance handles and will serve as a basis for the  
24 Writer or the Updater interfaces.

- 25 • register\_instance asks DDS to register an instance, which results in allocating it a local instance handle. The targeted  
26 instance is indicated by the key value in the passed data (datum).
- 27 • unregister\_instance asks DDS to unregister the instance, indicated by the passed instance\_handle and the key  
28 values of the passed data (datum) and thus to release the instance handle

29 Both operations are very similar to the DDS ones and are just passed to the DDS DataReader in support for the relater DDS  
30 port. Cf. the DDS documentation for more details. Any DDS error will be reported through an InternalError exception.

```

1 Interface Writer
2 of written
3 raises (InternalError);
4 attribute boolean is_coherent_write;nb write(in T$Seq instances) // returns unsigned long

```

### Interface MultiWriter

```

5 Interface MultiWriter
6 interface MultiWriter<typename T> { // T assumed to be a data type
7 typedef sequence<T> T$Seq;
8 };
9 interface Writer<typename T> { // T assumed to be a data type
10 void write (in T an_instance)
11 raises (InternalError);
12 };14590 - DDS port interfaces should be local
13 local interface Writer : InstanceHandleManager {
14 void write_one (in T datum, in DDS::InstanceHandle t instance_handle)
15 raises (InternalError);
16 void write_many (in TSeq data)
17 raises (InternalError);
18 attribute boolean is_coherent_write; // FALSE by default
19 };

```

20 Behavior of a **MultiWriter** is as follows: ~~between DDS begin\_coherent\_updates and an end\_coherent\_updates~~

- 21 • ~~The write orders are stopped at the first error (and the index of the erroneous instance is reported in the raised exception)embedded~~
- 22
- 23 • ~~If is\_coherent\_write is TRUE, the write orders are~~
- 24 • write\_one allows publishing one instance value. The targeted instance is designated by the passed instance handle (instance\_handle) if not **DDS::HANDLE\_NIL** or by the key values in the passed data (**datum**) otherwise. If a valid handle is passed, it must be in accordance with the key values of the passed data otherwise an **InternalError** exception is raised with the returned DDS error code. More generally, any DDS error when publishing the data will be reported by an **InternalError** exception.
- 25
- 26
- 27
- 28
- 29 • write\_many allows publishing a batch of instance values in a single operation. Resulting DDS orders are stopped at the first error (and the **index** of the erroneous instance value is reported in the raised **InternalError** exception). If the attribute **is\_coherent\_write** is **TRUE**, the resulting successful write DDS orders are placed between a **DDS begin\_coherent\_updates** and an **end\_coherent\_updates**.
- 30
- 31
- 32

---

### Issue 14567 - Updater and instance handle

### Interface Updater

```

33 Interface Updater
34
35 interface Updater<typename T> { // T assumed to be a data type
36 void create (in T an_instance)
37 raises (AlreadyCreated,
38 InternalError);
39 void update (in T an_instance)
40 raises (NonExistent,
41 InternalError);
42 void delete (in T an_instance)
43 raises (NonExistent,
44 InternalError);
45 readonly attribute boolean is_lifecycle_checked;
46 };14590 - DDS port interfaces should be local
47 local interface Updater : InstanceHandleManager {
48 void create_one (in T datum)
49 raises (AlreadyCreated,
50 InternalError);

```

```

1 | void update_one (in T datum, in DDS::InstanceHandle t instance handle)
2 | raises (NonExistent,
3 | InternalError);
4 | void delete_one (in T datum, in DDS::InstanceHandle t instance handle)
5 | raises (NonExistent,
6 | InternalError);
7 |
8 | void create_many (in TSeq data)
9 | raises (AlreadyCreated,
10 | InternalError);
11 | void update_many (in TSeq data)
12 | raises (NonExistent,
13 | InternalError);
14 | void delete_many (in TSeq data)
15 | raises (NonExistent,
16 | InternalError);
17 |
18 | readonly attribute boolean is_global_scope; // FALSE by default
19 | attribute boolean is_coherent_write; // FALSE by default
20 | };

```

21 | Behavior of an **Updater** is as follows:

- 22 | • ~~If `is_lifecycle_checked` is TRUE, then `create` checks that the instance is not already existing and `update` and `delete`~~  
23 | ~~that the instance is existing; `AlreadyCreated` and `NonExistent` exceptions may be raised.~~
- 24 | • ~~If `is_lifecycle_checked` is FALSE, then those checks are not performed.~~

25 | Note: This check may require an attempt to get the instance under the scene and cannot be a full guarantee as a write or a  
26 | dispose from another participant may always occur between the check and the actual write or dispose. Therefore it should be  
27 | restricted to architectures where a single writer is involved.

- 28 | • `create one` (resp. `update one`, `delete one`) allows creating (resp. updating, deleting) one instance. For `create one`  
29 | this instance is designated by the key value in `datum`. For the two others, it is designated by the passed instance  
30 | handle (`instance handle`) if not `DDS::HANDLE NIL` or by the key value in the passed instance data (`datum`)  
31 | otherwise. If a valid handle is passed, it must be in accordance with the key value of the passed instance data  
32 | otherwise an `InternalError` exception is raised with the returned DDS error code. More generally, any DDS error  
33 | when publishing the data will be reported by an `InternalError` exception.
- 34 | • `create many` (resp. `update many`, `delete many`) allows creating (resp. updating, deleting) several instances in a  
35 | single call. Resulting DDS orders are stopped at the first error (and the `index` of the erroneous instance value is  
36 | reported in the raised `InternalError` exception).  
37 | If the attribute `is_coherent_write` is TRUE, the resulting successful write or dispose DDS orders are placed between a  
38 | DDS `begin_coherent_updates` and an `end_coherent_updates`.
- 39 | • `create one` and `create many` operations check that the targeted instances are not existing prior to the call. This  
40 | check is performed locally to the component if the attribute `is_global_scope` is FALSE or globally to the data space if  
41 | `is_global_scope` is TRUE. In any case, this check is performed before any attempt ordering DDS to write and is  
42 | applied to all the submitted instances. All the erroneous instances are reported in the `AlreadyCreated` exception (by  
43 | means of their index in the submitted sequence)
- 44 | • `update one` and `update many` operations check that the targeted instances are existing prior to the call. This check  
45 | is performed locally to the component if the attribute `is_global_scope` is FALSE or globally to the data space if  
46 | `is_global_scope` is TRUE. In any case, this check is performed before any attempt ordering DDS to write and is  
47 | applied to all the submitted instances. All the erroneous instances are reported in the `NonExistent` exception (by  
48 | means of their index in the submitted sequence)
- 49 | • `delete one` and `delete many` operations check that the targeted instances are existing prior to the call. This check is  
50 | performed locally to the component if the attribute `is_global_scope` is FALSE or globally to the data space if  
51 | `is_global_scope` is TRUE. In any case, this check is performed before any attempt ordering DDS to dispose and is

1 | applied to all the submitted instances. All the erroneous instances are reported in the **NonExistent** exception (by  
2 | means of their index in the submitted sequence)

3 | Note: Global checks may require an attempt to get the instance under the scene and cannot be a full guarantee as a write or a  
4 | dispose from another participant may always occur between the check and the actual write or dispose. Therefore this setting  
5 | should be restricted to architectures where a single writer is involved.

---

**Issue 14212 - NonExistent::indexes with Reader/Getter/Writer**

---

6 | Note: In case of a single operation (**create one, update one or delete one**) failing on the life cycle check, the sequence  
7 | parameter of the exception (**AlreadyExisting or NonExistent**) will contain 0. ~~between DDS **begin\_coherent\_updates** and a~~  
8 | **end\_coherent\_updates**

- 9 | • The write or dispose orders are stopped at the first error (and the index of the erroneous instance is reported in the  
10 | raised exception) embedded of deleted instances

```
11 | _____ raises (NonExistent,  
12 | _____ InternalError);  
13 | _____ readonly attribute boolean is_lifecycle_checked;  
14 | _____ attribute boolean is_coherent_write;  
15 | _____ );
```

16 | Behavior of a **MultiUpdater** is as follows:

- 17 | • If **is\_lifecycle\_checked** is TRUE, then **create** checks that the instances are not already existing and **update** and  
18 | **delete** that the instances are existing; **AlreadyCreated** and **NonExistent** exceptions may be raised.

- 19 | • These checks are performed before any attempt to write or dispose and are applied to all the submitted instances. All  
20 | the erroneous instances are reported in the exceptions (by means of their index in the submitted sequence)

- 21 | • If **is\_lifecycle\_checked** is FALSE, then those checks are not performed.

- 22 | • If **is\_coherent\_write** is TRUE, the write orders are nb delete (in T\$Seq instances) ~~// returns unsigned long of~~  
23 | updated instances

```
24 | _____ raises (NonExistent,  
25 | _____ InternalError);  
26 | _____ nb update (in T$Seq instances) // returns unsigned long of created instances  
27 | _____ raises (AlreadyCreated,  
28 | _____ InternalError);  
29 | _____ nb create (in T$Seq instances) // returns unsigned long  
30 | interface MultiUpdater<typename T> { _____ // T assumed to be a data type  
31 | _____ typedef sequence<T> T$Seq;  
32 | _____
```

33 | **!**

### 34 | **8.2.2.1.2 Data Access – Subscribing side**

35 | **Preamble:** for all the following operations, **read** means implicitly "with no wait" and **get** means implicitly "with wait".

36 | Several interfaces allow to retrieve data values from DDS data readers:

- 37 | • A **Reader** allows ~~to read~~ reading one or several instance values on a given topic according to a given criterion, with  
38 | no wait.
- 39 | • A **Getter** allows to get one or several new values on a given topic according to a given criterion. It may block to get  
40 | the proper information.
- 41 | • A **RawListener** allows to get pushed with a new value on a given topic, according to a given criterion, regardless the  
42 | instance status.

- ~~A **StateListener** allows to get pushed with a new value on a given topic, according to a given criterion; Different operations are called depending on the instance state.~~
- ~~A **MultiListener** allows to get pushed with a sequence of new values on a given topic, according to a given criterion.~~

In addition, the following interfaces allow getting fresh values from a given topic:

- A **Getter** allows getting them in pull mode. It may block to get the proper information.
- A **Listener** allows getting them in push mode, regardless the instance status.
- A **StateListener** allows getting them in push mode when the instance status is a concern: different operations will be triggered according to the instance status.

The following IDL declarations for those interfaces and related types, are followed by explanations when needed:

### **Related Types**

```

enum AccessStatus {
    FRESH_INFO,
    ALREADY_SEEN
};

enum InstanceStatus {
    INSTANCE_CREATED,
    INSTANCE_FILTERED_IN,
    INSTANCE_UPDATED,
    INSTANCE_FILTERED_OUT,
    INSTANCE_DELETED
};

```

---

**Issue 14177 - For timestamp, is this the DDS source\_timestamp? If yes, rename the member to source\_timestamp**

---

```

struct ReadInfo {
    instance_rank; unsigned long
    AccessStatus access_status;
    InstanceStatus instance_status;
    DDS::Time_t timestamp;
    DDS::InstanceHandle_t instance handle;
    DDS::Time_t source timestamp;
    AccessStatus access_status;
    InstanceStatus instance_status;
};

```

```

typedef sequence<ReadInfo> ReadInfoSeq;

```

**ReadInfo** is the simplified version of DDS **SampleInfo**. Each read or gotten piece of data is accompanied with a **ReadInfo** which specifies:

- The DDS **instance handle**.
- The DDS **source timestamp**.
- Whether the value has already been seen or not by the component (**AccessStatus** **access\_status**).
- The instance status (**InstanceStatus** **instance status**) at the time of the sample. This status can be:
  - **INSTANCE\_CREATED** if this is the first time that the component sees that instance (the instance is then existing for the component);
  - **INSTANCE\_FILTERED\_IN** if an existing instance reenters the filter after having been filtered out;
  - **INSTANCE\_UPDATED** if an existing instance is modified and stays within the filter;

- 1 | • **INSTANCE\_FILTERED\_OUT** if an existing instance just stopped passing the filter;
  - 2 | • **INSTANCE\_DELETED** if the instance just stopped existing.
  - 3 | • **The DDS timestamp**
  - 4 | • **The belonging instance rank within the returned sequence (`instance_rank`)**
- 5 | The **instance status** is therefore a combination of several fields in the original DDS **SampleInfo**. Unfortunately, in the  
6 | current DDS, the fact that a data is filtered out is not reported. However as this is likely to change soon, the two statuses  
7 | **INSTANCE\_FILTERED\_IN** and **INSTANCE\_FILTERED\_OUT** have been added for provision. As long as this feature is not  
8 | available in DDS, a compliant implementation of this specification is not required to deliver those two statuses.
- 9 | The following figure shows how the three other values can be computed based on DDS returned information.

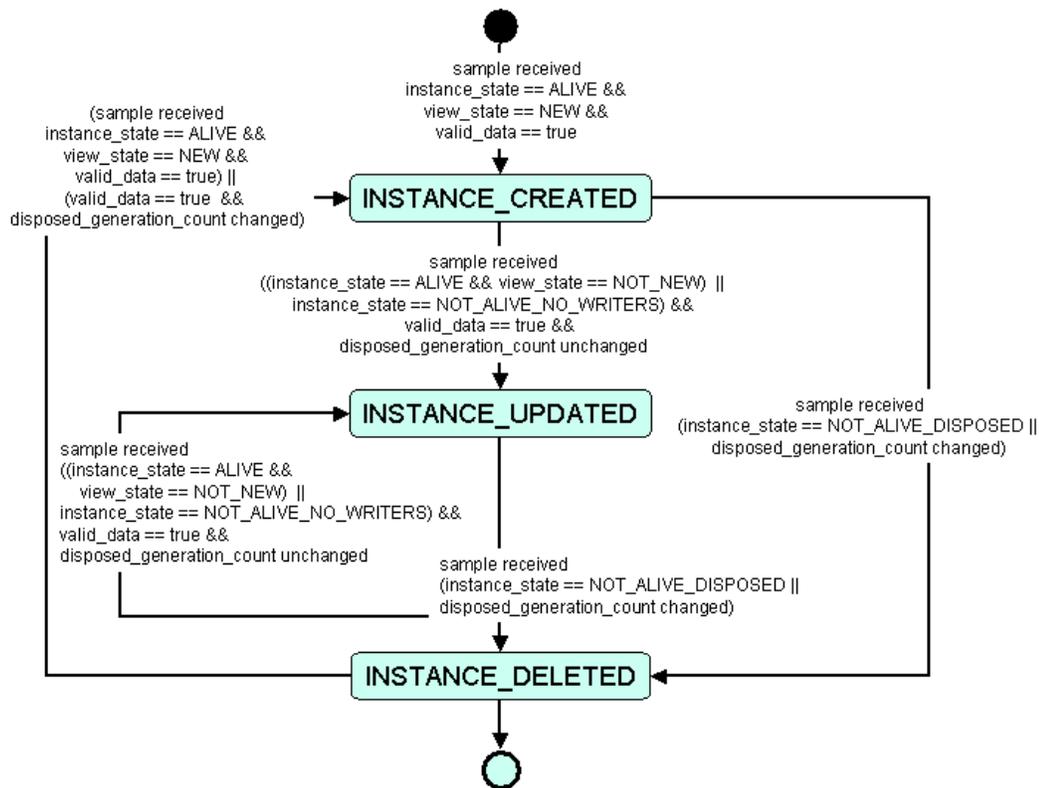

Figure 18: `ReadInfo::instance_status` State Chart

11 | Note: Except if the **instance status** is **INSTANCE\_DELETED**, the associated data value is valid (other cases where  
12 | `DDS::SampleInfo::valid_data` would be **FALSE** should be managed by the connector fragment and shouldn't be passed to the  
13 | component).

14 | Note: When several values are returned, they may be different samples of the same or of different instances. They will always  
15 | be ordered by instances (i.e. all the samples of the first instance, followed by all the samples of the second one...).

**Issue 13890 - Change on line 5 StringSeq to CORBAStringSeq**

```

16 | struct QueryFilter {
17 |     string          query;
18 |     DDS::StringSeq query_parameters
19 | };
  
```

**Issue 14174 - One line 24 the spec uses BadParameter, but it doesn't describe when this exception has to be thrown**

1 **QueryFilter** gathers in a single structure a query and its related parameters. The **QueryFilter** attribute placed on the  
 2 following **Reader** interfaces acts as a filter for all the read or get operations made through a port where such a Reader is  
 3 attached. -A void in empty string query means no query.

4 This query and its related parameters are for DDS use and must comply with DDS rules (c.f. DDS specification for more  
 5 details). Any attempt to set the attribute with values that are not accepted by DDS will result in a **InternalError** exception.

## 6 **Interface Reader**

```

7
8 interface Reader <typename T> { // T assumed to be a data type
9     typedef sequence<T> T$Seq;
10    void read_all (out T$Seq instances, out ReadInfoSeq infos)
11        raises (InternalError);
12    void read_all_history (out T$Seq instances, out ReadInfoSeq infos)
13        raises (InternalError);
14    void read_one (inout T an_instance, out ReadInfo info)
15        raises (NonExistent,
16                InternalError);
17    void read_one_history (in T an_instance,
18                          out T$Seq instances, out ReadInfoSeq infos)
19        raises (NonExistent,
20                InternalError);
21    attribute QueryFilter filter
22        setraises (BadParameter);
23 };
24 local interface Reader {
25     void read_last (out TSeq data, out ReadInfoSeq infos)
26         raises (InternalError);
27     void read_all (out TSeq data, out ReadInfoSeq infos)
28         raises (InternalError);
29     void read_one_last (inout T datum, out ReadInfo info,
30                       in DDS::InstanceHandle t instance handle)
31         raises (NonExistent,
32                 InternalError);
33     void read_one_all (in T datum, out TSeq data, out ReadInfoSeq infos,
34                      in DDS::InstanceHandle t instance handle)
35         raises (NonExistent,
36                 InternalError);
37     attribute QueryFilter filter
38         setraises (InternalError);
39 };

```

40 Behavior of a **Reader** is as follows:

- 41 • Underlying DDS read operations will be performed with the following DDS access parameters:
  - 42 • **SampleStateMask**: **READ** or **NO\_READ\_**
  - 43 • **ViewStateMask**: **NEW** or **NOT\_NEW\_**
  - 44 • **InstanceStateMask**: **ALIVE\_**
  - 45 • **¶** through the query as specified in the **filter** (" " means no query)-
- 46 • **read\_all|last** returns the last sample of all instances. Any DDS error when reading the data will be reported by an  
 47 InternalError exception.
- 48 • **read\_all\_history** returns all samples of all instances. Any DDS error when reading the data will be reported by an  
 49 InternalError exception.

---

**Issue 14175 - if no key is specified the an instance is supposed to be empty?**

- 1 • **read\_one\_last** returns the last sample of a given instance; parameter **an\_instance** is supposed to be passed filled  
2 with the key value and will be passed back with all its fields. The targeted instance is designated by the passed instance  
3 handle (**instance handle**) if not **DDS::HANDLE\_NIL** or by the key value in the passed data (**datum**) otherwise. If a  
4 valid handle is passed, it must be in accordance with the key value of the passed data otherwise an **InternalError**  
5 exception is raised with the returned DDS error code. More generally, any DDS error when reading the data will be  
6 reported by an **InternalError** exception.  
7 In case the instance does not exist (no data are registered for that instance in DDS), the exception **NonExistent** is  
8 raised.  
9 In case of a keyless topic, the last value in the topic will be returned as DDS considers all values in such a topic as  
10 samples of one unique instance.
- 11 • **read\_one\_historyall** returns all the samples of a given instance; parameter **an\_instance** is supposed to be passed  
12 filled with the key value. The targeted instance is designated by the passed instance handle (**instance handle**) if not  
13 **DDS::HANDLE\_NIL** or by the key value in the passed data (**datum**) otherwise. If a valid handle is passed, it must be  
14 in accordance with the key value of the passed data otherwise an **InternalError** exception is raised with the returned  
15 DDS error code. More generally, any DDS error when reading the data will be reported by an **InternalError**  
16 exception.  
17 In case the instance does not exist (no data are registered for that instance in DDS), the exception **NonExistent** is  
18 raised.  
19 In case of a keyless topic, all values will be returned as DDS considers all values in such a topic as samples of one  
20 unique instance.

21 Note: This interface is the basis for a passive data reader (i.e. a component that just looks at the data as they are). It is also  
22 very useful for the reactive data getters (i.e. components that need to react to new data, whether they choose to get them in  
23 pull mode or be notified in push mode) in their initialization phase. This is the reason why all the DDS ports on the  
24 subscribing side will embed a **Reader** basic port.

## 25 **Interface Getter**

```
26  
27 interface Getter<typename T> {  
28     typedef sequence<T> T$Seq;  
29     boolean get_all (out T$Seq instances, out ReadInfoSeq infos)  
30     raises (InternalError);  
31     boolean get_all_history (out T$Seq instances, out ReadInfoSeq infos)  
32     raises (InternalError);  
33     boolean get_one (inout T an_instance, out ReadInfo info)  
34     raises (NonExistent,  
35     InternalError);  
36     boolean get_one_history (in T an_instance,  
37     out T$Seq instances, out ReadInfoSeq infos)  
38     raises (NonExistent,  
39     InternalError);  
40     boolean get_next (out T an_instance, out ReadInfo info)  
41     raises (InternalError);  
42     attribute QueryFilter filter  
43     setraises (BadParameter);  
44     attribute DDS::Duration_t time_out;  
45     };
```

14590 - DDS port interfaces should be local

```

1 | local interface Getter {
2 |     boolean get_one (out T datum, out ReadInfo info)
3 |         raises (InternalError);
4 |     boolean get_many (out TSeq data, out ReadInfoSeq infos)
5 |         raises (InternalError);
6 |     attribute DDS::Duration t      time out;
7 |     attribute DataNumber t      max delivered data; // default 0 (no limit)
8 | };

```

9 Behavior of a **Getter** is as follows:

- 10 • **Get** operations are performed with the following parameters
  - 11 • **SampleStateMask**: **NO\_READ\_**
  - 12 • **ViewStateMask**: **NEW** or **NOT\_NEW\_**
  - 13 • **InstanceStateMask**: **ALIVE** or **NOT\_ALIVE\_**
  - 14 • Through the query as specified in the filter (" " means no query)(if any) of the Reader associated to the port,
  - 15 • Within the time limit specified in **time\_out**.

---

**Issue 13963 - why not use an exception instead of a return value for the methods in Getter<>?**

- 16 • They all ~~receives~~return as result a **boolean as result** that indicates ing whether actual data are provided (**trueTRUE**) or  
17 if the time-out occurred (**falseFALSE**).
- 18 • **get\_allone** returns the lastnext sample of all instanceesto be gotten.
- 19 • **get\_all\_historymany** returns all the available samples of all instanceesin the limits set by the attribute  
20 max delivered data. In case there are more available samples, the first **max delivered data** are returned. The  
21 default value for that attribute is UNLIMITED (0)**get\_one** returns the last sample of a given instance; parameter  
22 **an\_instance** is supposed to be passed filled with the key value and will be passed back with all its fields.
- 23 • **get\_one\_history** returns all the samples of a given instance; parameter **an\_instance** is supposed to be passed filled  
24 with the key value.
- 25 • **get\_next** returns each gotten samples, one by one.

26 Note: get\_all or get\_all\_history are especially useful in the application init phase.

## 28 **Interface RawListener**

```

29 |
30 | interface RawListener<typename T> {
31 |     void on_data (in T an_instance, in ReadInfo info);
32 | };14590 - DDS port interfaces should be local
33 | local interface Listener {
34 |     void on_one_data (in T datum, in ReadInfo info);
35 |     void on_many_data (in TSeq data, in ReadInfoSeq infos);
36 | };

```

37 Behavior of a **RawListener** is as follows:

- 38 • The semantics of **on\_one\_data** is similar to the one of **Getter::get\_nextone**, except that it is in push mode instead of  
39 pull mode.
- 40 • The semantics of on\_many\_data is similar to the one of Getter::get\_many, except that it is in push mode instead of  
41 pull mode.

- The operations are called according to the listener **mode** as set in the associated **DataListenerControl** (cf. Section 8.2.2.1.3). The mode can be
  - **NOT\_ENABLED**: none of these operations are called.
  - **ONE BY ONE**: the data are delivered one sample at a time through the on\_one\_data operation.
  - **MANY BY MANY**: the data are delivered, through the on\_many\_data operation, by groups of samples, according to the max\_delivered\_data limit set in the associated **DataListenerControl**.
- Query filter (if any) will be found in the associated **Reader** ~~(see below — definition of DDS extended ports).~~

## Interface **StateListener**

```

interface StateListener<typename T> {
    void on_creation (in T an_instance, in DDS::Time_t timestamp);
    void on_update (in T an_instance, in DDS::Time_t timestamp);
    void on_deletion (in T an_instance, in DDS::Time_t timestamp);
};
1490 - DDS port interfaces should be local
local interface StateListener {
    void on_creation (in T datum, in ReadInfo info);
    void on_one_update (in T datum, in ReadInfo info);
    void on_many_updates (in TSeq data, in ReadInfoSeq infos);
    void on_deletion (in T datum, in ReadInfo info);
};

```

Behavior of a **StateListener** is as follows: ~~that form the key.inees~~

- ~~The semantics of the operations is similar to the one of **Getter::get\_next**, except that it is in push mode instead of pull mode and that the exact operation called depends on the state of the instance:~~
  - ~~**on\_creation** is called when a new instance is delivered;~~
  - ~~**on\_update** is called when an already existing instance is updated;~~
  - ~~**on\_deletion** is called when an instance is said as non longer alive by underlying DDS; in this case, the only fields valid in the provided instance parameter are the~~
- No operation is called if the **mode** of the associated **StateListenerControl** is **NOT\_ENABLED**.
- **on\_creation** is triggered if the instance is considered as new in the component scope; note that in case there is a filter in the **Reader** associated to the port and the attribute **is\_filter\_interpreted** of the listener control is **TRUE**, this gathers also the case when the instance is filtered in.
- **on\_deletion** is triggered if the instance is no more existing; note that in case there is a filter in the **Reader** associated to the port and the attribute **is\_filter\_interpreted** of the listener control is **TRUE**, this gathers also the case when the instance is filtered out. The only fields valid in the provided **datum** parameter are the ones that make the key.
- **on\_one\_update** is triggered if neither **on\_creation** nor **on\_deletion** apply and the mode of the associated listener control is **ONE BY ONE**
- **on\_many\_updates** is triggered if neither **on\_creation** nor **on\_deletion** apply and the mode of the associated listener control is **MANY BY MANY**. The number of returned samples is within the limits of the attribute **max\_delivered\_data** of the associated listener control.
- Query filter (if any) will be found in the associated **Reader**.
- ~~**n\_data** is here called with a sequence of new values. Depending of **grouping\_mode**, each sequence will contain 1) all the samples of an instance, 2) all new last samples or 3) all new samples.~~

```

1 | • Query filter (if any) will be found in the associated Reader (see below definition of DDS extended ports).
2 | MultiListener
3 | enum GroupingMode {
4 | INSTANCE_HISTORY,
5 | LAST_SAMPLE_ALL_INSTANCES,
6 | ALL_SAMPLES_ALL_INSTANCES
7 | };
8 |
9 | interface MultiListener<typename T>{
10 | typedef sequence<T> T$Seq;
11 | void on_data (in T$Seq instances, in ReadInfoSeq infos);
12 | attribute GroupingMode grouping_mode;
13 | };

```

Behavior of a **MultiListener** is as follows:

- **14117 - ListenerControl**

### 8.2.2.1.3 Data Listener Control

The following interface allows to enable the listeners that are attached to the port. The initial value of the attribute is false meaning that the listeners are a priori not enabled. Controlling the data listener attached to the port to which they are attached. There are two data listener controls:

- **DataListenerControl** which embed the basic controlling behavior for any kind of data listeners;
- **StateListenerControl** which is a specialization of the former which add extra feature for a **StateListener**.

#### Interface DataListenerControl

```

23 | interface ListenerControl {
24 | attribute boolean enabled;
25 | };
26 | enum ListenerMode {
27 | NOT_ENABLED,
28 | ONE_BY_ONE,
29 | MANY_BY_MANY
30 | };

```

---

**Issue 14590 - DDS port interfaces should be local**

```

31 | local interface DataListenerControl {
32 | attribute ListenerMode mode; // default NOT_ENABLED
33 | attribute DataNumber t max_delivered_data; // default 0 (no limit)
34 | };

```

The two attributes of a **DataListenerControl** allows controlling the associated data listener as follows:

- If the **mode** is **NOT\_ENABLED**, the associated listener's operations are not triggered. This is the default setting as it allows the component to perform its initialization phase (likely using the associated **Reader**) before receiving any data notifications.
- If the **mode** is **ONE\_BY\_ONE**, the unitary operations (i.e. **on one data** or **on one update**) of the associated listener are triggered.
- If the **mode** is **MANY\_BY\_MANY**, the grouped operations (i.e. **on many data** or **on many updates**) of the associated listener are triggered. These operations are called with as many relevant samples as available, possibly limited by the value of **max\_delivered\_data**. The default value for that attribute is **UNLIMITED (0)**.

#### StateListenerControl

---

**Issue 14590 - DDS port interfaces should be local**

```

1 | local interface StateListenerControl : DataListenerControl {
2 |     attribute boolean is_filter_interpreted; // default FALSE
3 | };

```

4 | This listener control, specific to control a **StateListener**, extends the former **DataListenerControl** with the attribute  
5 | **is\_filter\_interpreted**.

- 6 | • If **TRUE**, the associated listener should consider an instance entering in (resp. going out) the filter (if any) of the  
7 | related **Reader**, as an instance creation (resp. deletion) and thus trigger the operation **on creation** (resp.  
8 | **on deletion**).
- 9 | • If **FALSE**, those events should be considered as normal instance updates and thus lead to triggering **on one update**  
10 | or **on many updates**, depending on the **mode**.

11 | Note: DDS is not currently reporting that an instance has been filtered out. This behavior has been thus added for provision. A  
12 | compliant implementation of this specification is not required to support it as long as DDS does not report when instances are  
13 | filtered out.

#### 14 | **8.2.2.1.4 Status Access**

15 | DDS is communicating errors or warnings by means of statuses. Some of those statuses are relevant for the component author  
16 | (e.g., sample lost), others are meaningful system wide (e.g. incompatible QoS) while others carry information that are needed  
17 | for functioning (e.g. data on readers).

- 18 | • The first ones are made available through a **PortStatusListener**; as those statuses may only concern a DDS data  
19 | reader, a **PortStatusListener** is meaningful only on a DDS port related to subscribing.
- 20 | • The second ones are made available through a **ConnectorStatusListener**
- 21 | • The last ones are kept for internal implementation of connectors fragments and therefore not reported.

#### 22 | **Interface PortStatusListener**

---

**Issue 14590 - DDS port interfaces should be local**

```

23 | local interface PortStatusListener { // status that are relevant to the component
24 |     void on_requested_deadline_missed(
25 |         in DDS::DataReader the_reader,
26 |         in DDS::RequestedDeadlineMissedStatus status);
27 |     void on_sample_lost(
28 |         in DDS::DataReader the_reader,
29 |         in DDS::SampleLostStatus status);
30 | };

```

#### 31 | **Interface ConnectorStatusListener**

---

**Issue 14590 - DDS port interfaces should be local**

```

1  local interface ConnectorStatusListener { // status that are relevant system-wide
2      void on_inconsistent_topic(
3          in DDS::Topic the_topic,
4          in DDS::InconsistentTopicStatus status);
5      void on_requested_incompatible_qos(
6          in DDS::DataReader the_reader,
7          in DDS::RequestedIncompatibleQosStatus status);
8      void on_sample_rejected(
9          in DDS::DataReader the_reader,
10         in DDS::SampleRejectedStatus status);
11     void on_offered_deadline_missed(
12         in DDS::DataWriter the_writer,
13         in DDS::OfferedDeadlineMissedStatus status);
14     void on_offered_incompatible_qos(
15         in DDS::DataWriter the_writer,
16         in DDS::OfferedIncompatibleQosStatus status);

```

---

**Issue 14017 - Section 8.2.2.1.4 and annex A missing parameter name**

```

17     void on_unexpected_status (
18         in DDS::Entity the_entity,
19         in DDS::StatusKind status_kind);
20 };

```

21 All the operations of those two listeners mimic exactly the related DDS ones, with exactly the same operation name and  
22 parameters.

23 In addition a last operation is added on **ConnectorStatusListener** to report unexpected statuses (**on\_unexpected\_status**).  
24 The two parameters are then the reporting DDS Entity and the DDS status kind.

### 25 8.2.2.2 DDS-DCPS Extended Ports

26 All the interfaces presented in the previous section, can be considered as building blocks to be assembled to form the  
27 extended ports:

---

**Issue 14214 - Do we need the Multi\* interfaces/ports?**

28 The following are defined:

```

29
30 porttype DDS_Write<typename T> {
31     uses Writer<T> _____ data;
32     uses DDS::DataWriter _____ dds_entity;
33 };
34
35 porttype DDS_MultiWrite<typename T> {
36     uses MultiWriter<T> _____ data;
37     uses DDS::DataWriter dds_entity;
38 };
39
40 porttype DDS_Update<typename T> {
41     uses Updater<T> _____ data;
42     uses DDS::DataWriter _____ dds_entity;
43 };
44
45 porttype DDS_MultiUpdate<typename T> {
46     uses MultiUpdater<T> _____ data;
47     uses DDS::DataWriter dds_entity;
48 };
49

```

```

1 | porttype DDS_Read<typename T> {
2 |     uses Reader<T> _____ data;
3 |     uses DDS::DataReader _____ dds_entity;
4 |     provides PortStatusListener _____ status;
5 | };
6 |
7 | porttype DDS_Get<typename T> {
8 |     uses Reader _____ data;
9 |     uses Getter<T> _____ -fresh data;
10 |    uses DDS::DataReader _____ dds_entity;
11 |    provides PortStatusListener _____ status;
12 | };
13 |
14 | porttype DDS_Raw Listen<typename T> {
15 |     uses Reader<T> _____ -data;
16 |     uses DataListenerControl _____ data control;
17 |     provides RawListener<T> _____ data listener;
18 |     uses DDS::DataReader _____ dds_entity;
19 |     provides PortStatusListener _____ status;
20 | };
21 |
22 | porttype DDS_StateListen<typename T> {
23 |     uses Reader<T> _____ -data;
24 |     uses StateListenerControl _____ data control;
25 |     provides StateListener<T> _____ data listener;
26 |     uses DDS::DataReader _____ dds_entity;
27 |     provides PortStatusListener _____ status;
28 | };
29 |
30 | porttype DDS_MultiListen<typename T> {
31 |     uses Reader<T> data;
32 |     uses ListenerControl control;
33 |     provides MultiListener<T> listener;
34 |     uses DDS::DataReader dds_entity;
35 |     provides PortStatusListener status;
36 | }

```

37 All proposed DDS ports combine at least a basic port to access data with a basic port to access underlying DDS entity.  
38 **DDS\_RawListenGet**, **DDS\_StateListen** and **DDS\_MultiS\_StateListen** split the data access functionality in two ports; the  
39 first one (**Reader**) is there to set the read criterion and provide operations for the initialization phase, while the second one  
40 (**Getter**, **Listener** or **StateListener**) is rather intended to be used in the application processing loop. All the ports intended for  
41 the subscribing side comprise also a port to be notified of the relevant statuses.

## 42 8.3 DDS-DCPS Connectors

43 DDS-DCPS connectors are intended to gather the connector fragments for all possible roles in a given DDS use pattern.

44 They come with several DDS-DCPS supported ports (which are expressed in the connector as mirror ports), each of them  
45 corresponding to a given role within this pattern as well as with related DDS entities and QoS setting.

46 As DDS-DCPS ports, DDS-DCPS connectors are parameterized by a data type. As they are very similar to components (from  
47 the D&C standpoint), they have configuration properties which allow to specify, all the elements that are needed to properly  
48 instantiate them, namely:

- 49 • The name of the DDS Topic which is associated to the data type,
- 50 • The list of fields making up the key for that Topic,
- 51 • The DDS Domain Id,

- 1 • The QoS settings that are to be applied to the underlying DDS entities (how these settings are expressed is explained  
2 in section 8.4).
- 3 Having all these information gathered at the connector-level (rather than split in each DDS participants) gives the ability to  
4 better master system consistency.
- 5 In addition, they provide a port to report configuration errors (e.g. to be used i.e. by a supervision service).

### 6 8.3.1 Base Connectors

7 **DDS\_Base** connector uses a **ConnectorStatusListener** port for reporting configuration errors and contains **read-only**  
8 attributes to store the Domain identifier and the QoS profile (c.f. section 8.4.2 for more details on QoS profile). The QoS  
9 profile could be given either as a file URL or as the XML string itself.

10 Any attempt to change those attributes once the configuration is complete will raise a **NonChangeable** exception.

11 All DDS connectors should inherit from that base.

---

#### Issue 14574 - topic\_name attribute

```

12 connector DDS_Base {
13     uses ConnectorStatusListener          error_listener;
14     readonlyattribute DDS:DomainId_t    _____ domain_id
15     _____
16     readonlyattribute string            _____ qos_profile;    // File URL or XML string
17     _____
18     };

```

19 **DDS\_TopicBase** extends the **DDS\_Base** with the name of one topic and its key description. ~~the~~**DDS\_TopicBase** should be  
20 the base for all mono-topic connectors.

---

#### Issue 13890 - Change on line 5 StringSeq to CORBAStringSeq

#### Issue 13893 - line 27, change attribute to attribute also change StringSeq to CORBAStringSeq

```

21 connector DDS_TopicBase : DDS_Base {
22     readonlyattribute string            _____ topic_name
23     _____
24     readonlyattribute DDS::StringSeq    _____ key_fields
25     _____
26     };

```

27 As the attributes of **DDS\_Base**, the attributes of **DDS\_TopicBase** are also non changeable once configured. Any attempt to  
28 change them once the configuration is complete will raise a **NonChangeable** exception.

### 29 8.3.2 Pattern State Transfer

30 This pattern corresponds to participants that publish the state of data they manage (role **observable**), associated with other  
31 participants that subscribe to get the information (role **observer**). All those roles relate to the connector's topic.

32 Observers can be of various kinds:

- 33 • **passive\_observer** are just reading the state when they want.
- 34 • **pull\_observer** are getting the state changes.
- 35 • **push\_observer** are being notified with the state changes.

---

#### Issue 14214 - Do we need the Multi\* interfaces/ports?

- 36 • **push\_state\_observer** are being notified with the state changes with different operations depending on the instance  
37 status.

1 The connector definition is as follows:

```
2 connector DDS_State<typename T> : DDS_TopicBase { //T assumed to be a data type
3     mirrorport DDS_Update<T> observable;
4     mirrorport DDS_Read<T> passive_observer;
5     mirrorport DDS_Get<T> pull_observer;
6     mirrorport DDS_Listen push_observer;
7     mirrorport DDS_StateListen<T> push_state_observer;
8 };
```

9 Typically, with this pattern, **HISTORY QoS** should be set to **KEEP\_LAST**

### 10 8.3.3 Pattern Event Transfer

11 This pattern corresponds to participants sending events over DDS (role **supplier**), while other consume them (role **consumer**). All those roles relate to the connector's topic.

13 Consumers can be of various kinds:

- 14 • **pull\_consumer** are getting the events
- 15 • **push\_consumer** are being notified with the events

16 The connector definition is as follows:

---

**Issue 14214 - Do we need the Multi\* interfaces/ports?**

```
17 connector DDS_Event<typename T> : DDS_TopicBase { //T assumed to be a data type
18     mirrorport DDS_Write<T> supplier;
19     mirrorport DDS_Get<T> pull_consumer;
20     mirrorport DDS_Listen<T> push_consumer;
21 };
```

22 Typically, with this pattern, **HISTORY QoS** should be set to **KEEP\_ALL**

## 23 8.4 Configuration and QoS Support

### 24 8.4.1 DCPS Entities

25 When the connector fragments are deployed, they must create under the scene the DDS entities that are needed to get the wanted interaction.

27 As they are defined, the DDS ports are related to one data type and should therefore be attached one **DataReader** and/or **DataWriter**, which are entirely dedicated to their port.

29 The allocation rule for the **Subscriber**, **Publisher** and **DomainParticipant** is less straightforward as they may be allocated to the port or to the component (meaning that they will be shared by the ports of that component) or to the container (meaning that they will be shared by the components running in that container). Consequently, even if the QoS requirements are expressed on a port basis, components and containers can be given DDS entities that can be used by the infrastructure for servicing embedded ports if they meet the port requirements.

### 34 8.4.2 DDS QoS Policies in XML

35 To ease the consistent management of DDS QoS settings, this specification defines *QoS profiles*. A QoS profile takes the form of a XML string and can gather *QoS*<sup>11</sup> for several DDS entities that form a whole.

---

<sup>11</sup> A QoS is the set of QoS policies for a given DDS entity (DataReader, DataWriter...)

1 The following sections explain how to build QoS Profiles in XML. The XML Schema as well as a QoS Profile with all  
2 default values QoS policies, as specified in [DDS], are in ~~Erreur : source de la référence non trouvée~~ Annex C: -and  
3 ~~Erreur : source de la référence non trouvée~~, Annex D: , respectively.

#### 4 8.4.2.1 XML File Syntax

5 The XML configuration file must follow these syntax rules:

- 6 • The syntax is XML and the character encoding is UTF-8.
- 7 • Opening tags are enclosed in `<>`; closing tags are enclosed in `</>`.
- 8 • A value is a UTF-8 encoded string. Legal values are alphanumeric characters. All leading and trailing spaces are  
9 removed from the string before it is processed.  
10 For example, "`<tag> value </tag>`" is the same as "`<tag>value</tag>`".
- 11 • All values are case-sensitive unless otherwise stated.
- 12 • Comments are enclosed as follows: `<!-- comment -->`.

- 13 • The root tag of the configuration file must be `<dds_ccm>` and end with `</dds_ccm>`.
- 14 • The primitive types for tag values are specified in the following table:

Table 15: QoS Profile: Supported Tag Values

Type	Format	Notes
Boolean	yes, 1, true or <b>BOOLEAN_TRUE</b> : these all mean TRUE	Not case-sensitive
	no, 0, false or <b>BOOLEAN_FALSE</b> : these all mean FALSE	
Enum	A string. Legal values are the ones defined for QoS Policies in the DCPS IDL of DDS specification [DDS]	Must be specified as a string. (Do not use numeric values.)
Long	-2147483648 to 2147483647 or 0x80000000 to 0x7fffffff or <b>LENGTH_UNLIMITED</b>	A 32-bit signed integer
UnsignedLong	0 to 4294967296 or 0 to 0xffffffff	A 32-bit unsigned integer

#### 15 8.4.2.2 Entity QoS

16 To configure the QoS for a DDS Entity using XML, the following tags have to be used:

- 17 • `<participant_qos>`
- 18 • `<publisher_qos>`
- 19 • `<subscriber_qos>`
- 20 • `<topic_qos>`
- 21 • `<datawriter_qos>`
- 22 • `<datareader_qos>`

1 Each QoS is identified by a name. The QoS can inherit its values from other QoSs described in the XML file. For example:

```
2 <datawriter_qos name="DerivedWriterQos" base_name="BaseWriterQos">
3   <history>
4     <kind>KEEP_ALL_HISTORY_QOS</kind>
5   </history>
6 </datawriter_qos>
```

---

**Issue 13894 - line 8, shouldn't DDS\_KEEP\_ALL\_HISTORY\_QOS be replaces with KEEP\_ALL\_HISTORY\_QOS**

---

7 In the above example, the writer QoS named '**DerivedWriterQos**' inherits the values from the writer QoS '**BaseWriterQos**'.  
8 The **HistoryQosPolicy** kind is set to **DDS\_KEEP\_ALL\_HISTORY\_QOS**.

9 Each XML tag with an associated name can be uniquely identified by its fully qualified name in C++ style. The writer, reader  
10 and topic QoSs can also contain an attribute called **topic\_filter** that will be used to associate a set of topics to a specific QoS  
11 when that QoS is part of a DDS profile. See section 8.4.2.3.2.

#### 12 **8.4.2.2.1 QoS Policies**

13 The fields in a **QosPolicy** are described in XML using a 1-to-1 mapping with the equivalent IDL representation in the DDS  
14 specification [[DDS](#)]. For example, the **Reliability QosPolicy** is represented with the following structures:

```
15 struct Duration_t {
16     long sec;
17     unsigned long nanosec;
18 };
19
20 struct ReliabilityQosPolicy {
21     ReliabilityQosPolicyKind kind;
22     Duration_t max_blocking_time;
23 };
```

24 The equivalent representation in XML is as follows:

```
25 <reliability>
26   <kind></kind>
27   <max_blocking_time>
28     <sec></sec>
29     <nanosec></nanosec>
30   </max_blocking_time>
31 </reliability>
```

#### 32 **8.4.2.2.2 Sequences**

33 In general, the sequences contained in the QoS policies are described with the following XML format:

```
34 <a_sequence_member_name>
35   <element>...</element>
36   <element>...</element>
37   ...
38 </a_sequence_member_name>
```

39 Each element of the sequence is enclosed in an **<element>** tag., as shown in the following example:

```
40 property>
41   <value>
42     <element>
43       <name>my name</name>
44       <value>my value</value>
45     </element>
46     <element>
47       <name>my name2</name>
48       <value>my value2</value>
49     </element>
```

```
1         </value>
2     </property>
```

3 A sequence without elements represents a sequence of length 0. For example:

```
4     <a_sequence_member_name/>
```

5 As a special case, sequences of octets are represented with a single XML tag enclosing a sequence of decimal / hexadecimal values between 0..255 separated with commas. For example:

```
7     <user_data>
8         <value>100,200,0,0,0,223</value>
9     </user_data>
10    <topic_data>
11        <value>0xff,0x00,0x8e,0xEE,0x78</value>
12    </topic_data>
```

### 13 **8.4.2.2.3 Arrays**

14 In general, the arrays contained in the QoS policies are described with the following XML format:

```
15     <an_array_member_name>
16         <element>...</element>
17         <element>...</element>
18         ...
19     </an_array_member_name>
```

20 Each element of the array is enclosed in an **<element>** tag.

21 As a special case, arrays of octets are represented with a single XML tag enclosing an array of decimal/hexadecimal values between 0..255 separated with commas. For example:

```
23     <datareader_qos>
24         ...
25         <user_data>
26             <value>100,200,0,0,0,223</value>
27         </user_data>
28     </datareader_qos>
```

### 29 **8.4.2.2.4 Enumeration Values**

30 Enumeration values are represented using their IDL string representation. For example:

```
31     <history>
32         <kind>KEEP_ALL_HISTORY_QOS</kind>
33     </history>
```

### 34 **8.4.2.2.5 Time Values (Durations)**

35 Following values can be used for fields that required seconds or nanoseconds:

- 36 • **DURATION\_INFINITE\_SEC,**
- 37 • **DURATION\_ZERO\_SEC,**
- 38 • **DURATION\_INFINITE\_NSEC,**
- 39 • **DURATION\_ZERO\_NSEC.**

---

**Issue 13968 - Section 8.2.2.2.5 On line 5 DURATION\_INFINITE\_NSEC should be used**

---

1 The following example shows the use of time values

```
2 <deadline>
3   <period>
4     <sec>DURATION_INFINITE_SEC</sec>
5     <nanosec>DURATION_INFINITE_NSEC</nanosec>
6   </period>
7 </deadline>
```

### 8 8.4.2.3 QoS Profiles

9 A QoS profile groups a set of related QoS, usually one per entity. For example:

---

**Issue 13894 - line 8, shouldn't DDS\_KEEP\_ALL\_HISTORY\_QOS be replaces with KEEP\_ALL\_HISTORY\_QOS**

---

```
10 <qos_profile name="StrictReliableCommunicationProfile">
11   <datawriter_qos>
12     <history>
13       <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
14     </history>
15     <reliability>
16       <kind>DDS_RELIABLE_RELIABILITY_QOS</kind>
17     </reliability>
18   </datawriter_qos>
19   <datareader_qos>
20     <history>
21       <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
22     </history>
23     <reliability>
24       <kind>DDS_RELIABLE_RELIABILITY_QOS</kind>
25     </reliability>
26   </datareader_qos>
27 </qos_profile>
```

#### 28 8.4.2.3.1 QoS-Profile Inheritance

29 A QoS Profile can inherit its values from other QoS Profiles described in the XML file using the tag **base\_name**. For  
30 example:

```
31 <qos_profile name="MyProfile" base_name="BaseProfile">
32   ...
33 </qos_profile>
```

34 A QoS profile cannot inherit from other QoS profiles if the last one has not been parsed before.

#### 35 8.4.2.3.2 Topic Filters

36 A QoS profile may contain several writer, reader and topic QoSs, which can be selected based on the evaluation of a filter  
37 expression on the topic name.

---

**Issue 13894 - line 8, shouldn't DDS\_KEEP\_ALL\_HISTORY\_QOS be replaces with KEEP\_ALL\_HISTORY\_QOS**

---

38 The filter expression is specified as an attribute in the XML QoS definition thanks to a **topic\_filter** tag. For example:

```
39 <qos_profile name="StrictReliableCommunicationProfile">
40   <datawriter_qos topic_filter="A">
41     <history>
42       <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
43     </history>
44     <reliability>
45       <kind>DDS_RELIABLE_RELIABILITY_QOS</kind>
46     </reliability>
47   </datawriter_qos>
48   <datawriter_qos topic_filter="B*">
```

```

1         <history>
2 |         <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
3         </history>
4         <reliability>
5 |         <kind>DDS_RELIABLE_RELIABILITY_QOS</kind>
6         </reliability>
7         <resource_limits>
8             <max_samples>128</max_samples>
9             <max_samples_per_instance>128</max_samples_per_instance>
10            <initial_samples>128</initial_samples>
11            <max_instances>1</max_instances>
12            <initial_instances>1</initial_instances>
13        </resource_limits>
14    </datawriter_qos>
15    ...
16 </qos_profile>

```

17 If **topic\_filter** is not specified, the filter '\*' will be assumed. The QoSs with an explicit **topic\_filter** attribute definition will be  
18 evaluated in order; they have precedence over a QoS without a **topic\_filter** expression.

### 19 8.4.2.3.3 QoS Profiles with a Single QoS

20 The definition of an individual QoS is a shortcut for defining a QoS profile with a single QoS. For example:

---

**Issue 13894 - line 8, shouldn't DDS\_KEEP\_ALL\_HISTORY\_QOS be replaced with KEEP\_ALL\_HISTORY\_QOS**

---

```

21 <datawriter_qos name="KeepAllWriter">
22     <history>
23 |         <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
24     </history>
25 </datawriter_qos>

```

26 is equivalent to the following:

```

27 <qos_profile name="KeepAllWriter">
28     <writer_qos>
29         <history>
30 |             <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
31         </history>
32     </writer_qos>
33 </qos_profile>

```

## 34 8.4.3 Use of QoS Profiles

35 A QoS Profile shall be attached as a configuration attribute to a DDS connector. This profile should contain all values for  
36 initializing DDS Entities that are required by the connector.

37 In case of the connector involves several topics (which is not the case with the normative DDS-DCPS extended ports and  
38 connectors), then the **topic\_filter** feature of the QoS Profile may be used to properly allocate values to entities.

39 A QoS Profile could also be attached to a DDS-capable component (i.e. a component that has at least one DDS port) to define  
40 component's default **DomainParticipant**, **Subscriber** and/or **Publisher**. These default entities should be used preferably if  
41 their setting is compatible with the QoS requested in the connector's profile. If they are not compatible, specific entities  
42 dedicated to the 'non-compatible' port will be created. In this component profile, any **topic\_qos**, **datareader\_qos** or  
43 **datawriter\_qos** is simply ignored.

44 In addition, a similar QoS Profile could be attached to a DDS-capable container (i.e. a container hosting DDS-capable  
45 components to define container's defaults that should be used in priority if suitable.

#### 1 **8.4.4 Other Configuration – Threading Policy**

2 As opposed to the DDS QoS policies which need to be managed system-wide, the threading policy is local to the component  
3 using a DDS port. The threading policy could be set at several levels:

- 4 • port (for all its facets)
- 5 • component (for all the facets of its ports)
- 6 • container (for all the facets of its components' ports)

7 When a facet is activated, the threadpool attached to the port; if there is no port's policy, the component's threadpool is used;  
8 if there is no component's one, the container's threadpool is used; if there is no container's policy, then the default is applied.

## 9 DDS-DLRL Application

This section instantiates the Generic Interaction Support described in section 7, in order to define ports and connectors for DDS-DLRL. This section assumes an a-priori knowledge of DDS specification (in particular of the DLRL part).

The rationale for providing support to DLRL flavor of CCM in CCM is very similar to the one that drives the DCPS support, namely simplify the use and enforce separation of concerns.

The DLRL principles have been to ease as much as possible the publication and reception of data by providing ability to define plain application objects whose some data members are mapped to DDS topics. Then plain object manipulation (creation, update, deletion) is automatically translated under the scene by the DLRL layer in DCPS publications, while similarly DCPS receptions are automatically turned in updating objects. This interface is very developer-friendly and can hardly be simplified.

In return, according to CCM principles, the setting of the DLRL infrastructure, namely the creation of the Cache and of the Object Homes, their registration as well as the adjustment if needed of the DCPS entities QoS (all this making up the DLRL configuration) can be put apart from the application code.

The design principles to identify DLRL ports and connectors is identical to DCPS application, in that:

- Ports will capture programming contracts for components
- Connectors will be the support for system-wide configuration.

### 9.1 Design Principles

#### 9.1.1 Scope of DLRL Extended Ports

In DLRL, the natural entry point to deal with objects of a given type is the related **ObjectHome** and all objects of a given **Cache** are very related and need to be managed consistently.

Consequently, a DLRL extended port should be created to give access to all objects of a given Cache. That extended port will contains one **receptacle** for each **ObjectHome** and another **receptacle** for the **Cache** functional operations (i.e. excluding all the operations that are related to configuration that will be for the only use of the **Connector** implementation).

#### 9.1.2 Scope of DLRL Connectors

A connector is the natural support to gather all the DLRL extended ports that are related to the same set of topics in order to master their configuration system-wide.

As potentially a DLRL object model (consistent set of DLRL classes and their relations) is specific to one participant, it could be as many DLRL extended ports as participants sharing the same set of DCPS topics. However, nothing prevents deploying several components using the same DLRL object model (therefore using the same extended port definition).

### 9.2 DDS-DLRL Extended Ports

Due to its essential variable composition, it is not possible to define one normative DLRL extended port. In return, the definition of their basic ports as well as the extended port composition rule are normative.

## 1 9.2.1 DLRL Basic Ports

### 2 9.2.1.1 Cache Operation

3 This interface is intended to type the **receptacle** dedicated to using the **Cache** once initialized by the infrastructure. It  
4 therefore contains only the operative subset of the **DDS::Cache** functions and attributes.

5 All the retained functions mimic exactly the **DDS::Cache** ones, and therefore request the same parameters and return the  
6 same result. Similarly, all the retained attributes are identical to the **DDS::Cache** ones.

---

Issue 14590 - DDS port interfaces should be local

---

```
7
8 | local interface CacheOperation {
9 |     // Cache kind
10 |     // -----
11 |     readonly attribute DDS::CacheUsage          cache_usage;
12 |
13 |     // Other Cache attributes
14 |     // -----
15 |     readonly attribute DDS::ObjectRootSeq  objects;
16 |     readonly attribute boolean             updates_enabled;
17 |     readonly attribute DDS::ObjectHomeSeq  homes;
18 |     readonly attribute DDS::CacheAccessSeq sub_accesses;
19 |     readonly attribute DDS::CacheListenerSeq listeners;
20 |
21 |     // Cache update
22 |     // -----
23 |     void DDS::refresh( )
24 |         raises (DDS::DCPSError);
25 |
26 |     // Listener management
27 |     // -----
28 |     void attach_listener (in DDS::CacheListener listener);
29 |     void detach_listener (in DDS::CacheListener listener);
30 |
31 |     // Updates management
32 |     // -----
33 |     void enable_updates ();
34 |     void disable_updates ();
35 |
36 |     // CacheAccess Management
37 |     // -----
38 |     DDS::CacheAccess create_access (in DDS::CacheUsage purpose)
39 |         raises (DDS::PreconditionNotMet);
40 |     void delete_access (in DDS::CacheAccess access)
41 |         raises (DDS::PreconditionNotMet);
42 | };
```

### 43 9.2.1.2 DLRL Class (ObjectHome)

44 For each DLRL object type to be part of the application, the DLRL extended port should comprise a **receptacle** of type the  
45 related home inheriting from **DDS::ObjectHome**. That class should have been generated by the DDS-DLRL product tooling.

46 All accesses to the DLRL objects of this type will be manageable through this entry point.

## 47 9.2.2 DLRL Extended Ports Composition Rule

48 DLRL extended ports are as many as applications. A DLRL extended port should be made of:

- 49 • A **CacheOperation** receptacle,

- 1 • As many **DDS:ObjectHome**-derived receptacles as DLRL object types that will be used by the component using that  
2 DLRL port (those types having been generated by the DDS-DLRL product tooling).

3 Following is an example of such a declaration:

---

**Issue 14611 - Module name**

---

```
4 porttype MyDirPort_1 {  
5 |     uses DDS_GCMCCM DDS::CacheOperation cache;  
6 |     uses FooHome foo_home; // entry point for Foo objects  
7 |     uses BarHome bar_home // entry point for Bar objects  
8 | };
```

9 Based on this information, the related connector fragment will, under the scene:

- 10 • Create the cache according to the specified **CacheOperation::cache\_usage**,
- 11 • Instantiate and register the specified **ObjectHome** (that will create the DCPS entities according to the DLRL → DCPS  
12 mapping),
- 13 • Apply the QoS profile to modify underlying DCPS entities (if specified in the connector),
- 14 • Enable the infrastructure so that DLRL objects can be created and used DLRL way.

## 15 9.3 DDS-DLRL Connectors

---

**Issue 13972 - Section 9.2.2 Line 16 doesn't read, line 33 should also be clear**

---

16 ~~A DLRL connector is also essentially variable in its composition for it contains as many mirror ports as there are different~~  
17 ~~object models to share the related topics. It~~ As a DLRL connector aims at gathering as many mirror ports as there are  
18 ~~different object models in the system sharing the related topics, its composition is essentially variable and application-~~  
19 ~~dependent and a unique standard DLRL connector cannot be defined. A DLRL connector~~ should inherit from the connector  
20 **DDS\_Base**, to be given a **ConnectorStatusListener** port, a domain id and a QoS profile attribute, and add as many mirror  
21 ports as there exist DLRL extended ports to share the related set of topics.

22 Following is an example of such a declaration:

---

**Issue 14611 - Module name**

---

```
23 | connector MyDirConnector : DDS_GCMCCM DDS::DDS_Base {  
24 |     mirrorport MyDirPort_1 p1;  
25 |     mirrorport MyDirPort_2 p2;  
26 |     mirrorport MyDirPort_3 p3;  
27 | };
```

## 28 9.4 Configuration and QoS Support

### 29 9.4.1 DDS Entities

30 As a DLRL port corresponds to one **Cache**, it must be given its own **Publisher** and/or **Subscriber** (depending on the cache  
31 usage). In addition, it will get as many **DataReaders** and/or **DataWriters** as there are topics used by the DLRL objects.

### 32 9.4.2 Use of QoS Profiles

---

**Issue 13972 - Section 9.2.2 Line 16 doesn't read, line 33 should also be clear**

---

33 Configuring DLRL ports can be achieved exactly with the same philosophy as for DCPS ports, with the same definition for a  
34 QoS Profile (see sections 8.4.2 and 8.4.3), except that, as the QoS Profile attached to the DLRL connector should contain  
35 values for all the topics involved, the **topic\_filter** feature of the QoS Profile is ~~likely~~ to be used in case there is a need to  
36 specify different QoS values for different topics.

## Annex E: QoS Policies for the DDS Patterns

(non normative)

The following tables summarizes the DDS QoS policies that are relevant for the two DDS patterns that have been selected (State Transfer Pattern as defined in section 8.3.2 and Event Transfer Pattern as defined in section 8.3.3)

In those tables the color code is as follows:

	Qos is not defined for that DDS entity or entity is not relevant for that role
	Default value changeable by the designer
	Value changeable by the designer
	Default value required by the pattern (invariant)
	Value required by the pattern (invariant)

Pattern	State
